THE progress of cancer research in Sydney has been increasingly rapid during the last eight years, since the University received, in 1921, the sum of £7,000 to be applied to this purpose. A committee which was formed to compile a programme of investigations to be undertaken came to the conclusion that a much larger income would be required than was available at the University, and a public appeal was launched which yielded £134,000. Laboratories were furnished and equipped, and researches were begun on various lines. Early in 1927 £100,000 was set aside by the Government of the Commonwealth to purchase radium for research in Australia; part of this fund was used to make available a radium clinic at the Royal Prince Alfred Hospital, New South Wales. The Cancer Research Committee of the University of Sydney, which was founded in 1921, was small at first, but soon increased in size and activity. It has now produced a *journal*, the first number of which, dated May 1st, 1929, has recently been received. The editors, Drs. H. G. Chapman and F. P. Sandes, are assisted by an editorial committee. A striking feature of this first issue is the amount of ground covered. Details are given by Dr. H. G. Chapman to illustrate the birth and steady growth of cancer research in New South Wales. Dr. J. H. L. Cumpston contributes a valuable statistical article on the incidence of cancer in Australia and on the measures taken to deal with it; the list of early indications of this disease, which was compiled by the Victorian Branch of the British Medical Association, is republished, and Dr. Cumpston's article ends with a warning that any suspicious sign should lead invariably to a prompt examination by an expert. Dr. Arthur Burrows comments on the results which may be expected from the purchase of radium by the Commonwealth, and discusses the ways in which radium can be employed to cure certain varieties of cancer or to relieve symptoms. Mr. W. H. Love deals with the subject of biophysics and the work of Professor Crowther on the reaction of tissue cells to *x*-ray exposure. The part played by trauma in producing cancer is critically discussed by Dr. H. M. Moran, who concludes that, while trauma reveals and aggravates this condition, the available evidence is too conflicting to justify any confident assertion. Dr. E. H. Molesworth contributes the first of a series of lectures on deep *x*-ray therapy, and Professor O. U. Vonwiller gives an outline of his introductory course on the physics of *x* rays and radium. All communications with regard to the journal should be addressed to the secretary of the Cancer Research Committee, University of Sydney, New South Wales.

A PROPOSED INSTITUTE OF MEDICAL PSYCHOLOGY

AN important development of the work of the National Council for Mental Hygiene and of the Tavistock Square Clinic is contemplated by a joint committee of these two organizations, which has under consideration a proposal to establish in London an Institute of Medical Psychology for the investigation and the early and preventive treatment of nervous breakdown and minor mental disorders in adults and children. The Tavistock Square Clinic, which would provide the nucleus of the proposed institute, was started nearly nine years ago, but the facilities, though sufficient at the beginning, have become inadequate to meet the increasing demand for treatment. Thus in 1920–21, 248 patients were treated at the clinic; during last year this number rose to 750. It is estimated that even this number could be doubled or trebled if there were the necessary accommodation, and on the staff of the clinic a certain number of medical officers on a whole-time basis with sufficient clinical assistants. At present there is a long waiting list, which has from time to time to be closed because some patients would have to remain on it for six months before they could receive treatment. Among those to whom treatment has to be refused on these grounds are some who have been referred by the London hospitals, police authorities, and police court magistrates—including a number on "probation," who have been sent from the courts for immediate treatment. It is claimed that of the patients who received treatment in the period 1920–27, 80 per cent. derived benefit, and that in the great majority of these the benefit was maintained or, as time went on, even increased. The joint committee suggests, therefore, that the work of the clinic would be usefully extended by the establishment of larger departments for the treatment of adults and children, the provision of adequate facilities for research, and the development on a large scale of the educational activities which the clinic has successfully carried out in the past. These proposals are set out concretely in a pamphlet issued by the joint committee; they include a scheme for extending the present clinic buildings, the establishment of a hostel where patients of limited means could stay during the period of their treatment, and of homes for the temporary accommodation, observation, and environmental treatment of maladjusted children, the institution of a fund sufficient to provide fellowships and studentships for medical men and women who wish to do research in psychotherapy or to train themselves in its practice, and to provide a research department, a lecture hall, and library. The estimated capital outlay for the completion of this scheme is £300,000, and the committee is launching an appeal for that amount. Donations may be given either to the general fund (in which case one-third of the amount will go to the National Council for Mental Hygiene, one-third to the Tavistock Square Clinic, and one-third to the Institute of Medical Psychology; or specifically earmarked for the clinic extension building, the hostel, the homes for maladjusted children, the fellowship fund, the endowment fund, the National Council for Mental Hygiene, or the Tavistock Square Clinic. If the donor mentions no appropriation the money will go to the general fund. Cheques should be made payable to the Institute of Medical Psychology, and sent to the secretary at 51, Tavistock Square, London, W.C.1.

HEALTH OF THE ROYAL AIR FORCE.

THE report on the Royal Air Force for the year 1928,[1] which has just been issued, follows the lines of previous years, except that in accordance with the recommendation of the Joint Medical Services Subcommittee on Tuberculosis a more detailed analysis of the incidence of phthisis in the Royal Air Force has been included. The health of the force at home and abroad compares favourably with that of previous years, and the high level of physical fitness has been well maintained. In 1928 there began an investigation into the effects of fast flying and intensive aerobatics; a special apparatus has been constructed for the investigation of the effects of fast horizontal turns, and it is proposed to use this in conjunction with an apparatus suggested by the director of scientific research for studying the effects of steep dives, etc. A certain number of successful pilots have been tested to ascertain the effects upon the pulse rate, blood pressure, and the ocular muscle balance. An attempt was made to estimate the prophylactic value of two varieties of influenza vaccine among the apprentices between the ages of 15 and 18 years living under similar conditions in barracks at Halton. It did not appear that inoculation with either of these two vaccines diminished the incidence of influenza or acute nasopharyngitis in any appreciable degree. Such influenza as occurred was of a very mild type, and, consequently, no

[1] Report on the Health of the Royal Air Force for the Year 1928. London: H.M. Stationery Office. 1929. Price 4s. net.

information was gained as to whether inoculation lessened the severity of the disease or of its complications. The report includes a short historical account of the transfer of casualties by air since the inception of this method of evacuation, with special reference to Iraq and Palestine. There are now no aircraft definitely allocated to medical use. The practice of employing a service type of aircraft, either for routine medical communication flights or, when specially requisitioned, for medical use, has proved satisfactory and economical.

MEDICAL INSURANCE AGENCY.

The annual general meeting of the Medical Insurance Agency Limited (by Guarantee) was held at the House of the British Medical Association on October 15th. The report then received covered the twenty-second year of the agency's work, and showed that the great expansion which is now taken as a matter of course had been experienced during the past year. The balance sheet, as certified by the auditors, was approved, and showed that the life assurance now dealt with through the agency approximates very closely to a total of one and three-quarter million pounds. Striking increases were also shown in the sections dealing with sickness and accident, motor car insurance, and comprehensive household policies. The total premiums for insurance business debited to the agency by the various companies with which its business is transacted amounted to £89,948. The rebates to medical practitioners insuring through the medium of the agency amounted to £4,187, and the total so saved to the medical profession during the life of the agency has been £33,085. The following grants were made to the organized medical charities for 1929:

		£	s.	d.
Royal Medical Benevolent Fund...		630	0	0
Royal Medical Benevolent Fund Guild ...		630	0	0
Epsom College—				
Dawson Williams Scholarship ...	£500			
Do., to replace sum spent in 1929	£150			
For votes	£210			
		860	0	0
Girls' Education Subcommittee...		250	0	0
Royal Home for Incurables, Putney		52	10	0
Sir Charles Hastings Fund		52	10	0
		£2,475	0	0

As a result of this distribution the total sum devoted to medical charities by the Medical Insurance Agency since 1910 has amounted to £22,880.

CONFERENCE ON MATERNITY SERVICES.

The Minister of Health and Laggard Local Authorities.

A fourth annual conference under the auspices of the Maternal Mortality Committee—a voluntary organization concerned for the protection of motherhood and for infant welfare—was held at the Central Hall, Westminster, on October 22nd, and was attended by some hundreds of women representing local authorities and societies for social service. Lady Cynthia Colville presided, and the principal speaker was the Minister of Health (Mr. Arthur Greenwood), who was accompanied by Miss Susan Lawrence (Parliamentary Secretary to the Ministry) and Sir George Newman (Chief Medical Officer). A report by the convening committee was placed before the conference, indicating what had been done during the last twelve months to advance its aims. The report of the Departmental Committee on the Training and Employment of Midwives was welcomed, and the Minister was urged to put into force as soon as possible the recommendations therein made concerning maternal care. In a reference to the memorandum on a national maternity service scheme issued by the British Medical Association, the Maternal Mortality Committee stated that the most interesting feature of the scheme was the emphasis it placed on the necessity for the improvement in the training of doctors in maternity work. A resolution assuring the Minister of the active and enthusiastic support of the conference in any action he might take upon the recommendations of the Departmental Committee on Midwives, so far as these concerned maternal care, was carried unanimously.

In an address, which was cordially received, Mr. Arthur Greenwood pointed out that the problem of maternal mortality was not only the loss, serious as it was, of 3,000 mothers a year, but the drain on the vitality of a large number of others whose health was permanently injured. On the occasion of the previous conference,[1] his predecessor, Mr. Neville Chamberlain, had referred to the setting up of two departmental committees, one on the problem of maternal mortality, and the other on midwives. The latter had now reported; the former was continuing its scientific investigations. He also acknowledged the good offices of the British Medical Association in putting forward a policy of reform, and, again, there were the recommendations of the Royal Commission on National Health Insurance. On the basis of these constructive proposals he hoped it would be possible to take effective action. The major proposals of the Departmental Committee on Midwives required legislation, but certain of its recommendations could be put into effect under existing powers. He intended to bring these recommendations as forcibly as he could to the notice of the local authorities, and he hoped also to deal with the larger questions of legislation.

Mr. Greenwood went on to say that, while the causes for the high rate of maternal mortality were not all understood, it was clear that the better the general health of the community, the better the chance for the mothers. The development of an energetic public opinion on health matters and the education of expectant mothers were of great importance. He was no opponent of further legislation on maternal mortality, but by no means all local authorities were using more than a fraction of the powers they possessed. A large number of them, whether owing to indifference, false economy, or lack of understanding of the importance of the subject, had not used the lever which was already to their hand. He was prepared to do all he could to stimulate local authorities to use their full powers. The expectant mother ought to have behind her the sympathy of the community, expressed through ante-natal clinics, midwives, the availability of a doctor, with a specialist in the background if necessary, and the provision of maternity hospitals when the domestic surroundings were not suitable. He hinted that at no distant date it might be possible to deal with these problems by comprehensive legislation, but the question had to be fitted into general provisions for maintaining and raising the standard of communal health and the system of social insurance.

After some representatives of local authorities had addressed the conference, Dr. H. B. Brackenbury claimed for the proposals of the British Medical Association that they were put forward before public attention had otherwise been drawn to the question. If the Minister would move in the direction of these proposals, he would be supported by professional and public opinion, which was ripe for action. Lady Barrett wound up the discussion by urging women voters to bring pressure to bear upon local authorities to do what Parliament had empowered them to do. There was evidently general agreement that every woman should have, during confinement, the attendance of a skilled midwife, and that a doctor should be called in at the beginning of pregnancy, and again at a later period, to ensure that all was well.

[1] *British Medical Journal*, November 3rd, 1928, p. 810.

On October 18th the Minister of Health received a deputation from the Garden Cities and Town Planning Association. The deputation was introduced by Mr. Cecil Harmsworth, and the speakers were Dr. F. E. Fremantle, M.P., Captain Reiss, Dr. Macfadyen, Mr. R. C. Wallhead, M.P., Alderman Culpin, and Miss Bushell. The deputation urged that new machinery is required in order to further the garden city movement; it asked that the Government should investigate the difficulties in the way of a more rapid development of garden cities under existing legislation, and also that a statutory body should be established to undertake the actual initiation of new garden city development. The Minister said, in reply, that he would give further and careful consideration to the suggestions which had been made to him.

Nova et Vetera.

JAMES BRAID OF MANCHESTER.*

BY

GEORGE FLETCHER, M.D., M.R.C.P.,

CONSULTANT TUBERCULOSIS OFFICER, LANCASHIRE COUNTY COUNCIL.

James Braid was a general practitioner who, in his day, won something of a European reputation. He died less than seventy years ago, and yet his doings and his writings alike are now difficult to retrieve. His biographies are scanty and sometimes erroneous in details; the year of his birth is mentioned with uncertainty, and in the last edition of a well-known history of medicine that of his death is wrongly given. His writings appeared for the most part in the form of small paper-backed pamphlets, which are now not easy to come by.

He was the son of James Braid and Anne Suttie, and was born on June 19th, 1795, in Fifeshire, where his father seems to have been a man of some substance. He matriculated at Edinburgh University in 1812 and remained there until 1815, when he took the diploma of the Royal College of Surgeons of that city. He served his apprenticeship with Mr. Anderson of Leith, a surgeon of some distinction, and soon after qualifying went to live at Leadhills in Lanarkshire, where he married and had a daughter and a son born to him. About eight years later he removed to Dumfries as a partner of Dr. William Maxwell, who is assuredly immortal, for he was the friend and physician of Robert Burns. Whilst here, Braid was called to attend a Manchester commercial traveller who had been slightly injured in a road accident, and was induced by him to turn his thoughts southwards. Accordingly, about the year 1826 he came to Manchester, where he set up in practice and remained until his sudden death on the morning of March 25th, 1860. He awoke complaining of chilliness and pain in the side, was given a drink of tea, and then sank back and died. There was an inquest, but no necropsy, and death was certified as having been due to "natural causes," of which the most likely seems to have been cerebral haemorrhage. He was buried at the parish church of Neston, Cheshire, where his son, James Braid, was in practice. In spite of a long and busy professional life he died a comparatively poor man, for his whole estate was valued at under £3,000.

His Manchester career was one of success and distinction, but he had little connexion with official medicine in the city. The fact is that his advocacy of hypnotism—an advocacy which strikes one now as having been temperate and reasonable—led to his being regarded by his more disciplined brethren as something of a charlatan. He had no connexion with the Infirmary, he was not a member of the Literary and Philosophical Society, and he took no part in the Medico-Ethical Association which was founded in 1849.

Braid first won distinction in the field of surgery. He specialized in the treatment of various deformities, and by the year 1841 he had operated on more than 900 cases of talipes, spinal curvature, and strabismus. He devised a new operation for paralytic talipes, and seems to have been the first man, in this country at any rate, to perform tendon shortening for this condition. His reputation brought him patients from all parts of the kingdom, while his results were so good that modern orthopaedists regard them with some perplexity.

The course of Braid's life was altered in November, 1841, when a travelling mesmerist named Lafontaine visited this city. Braid went to the demonstrations as a complete sceptic, but he took the trouble to examine the mesmerized subjects for himself, and soon concluded that there was something genuine in the condition. He set out to investigate the subject experimentally, and within a month we find him beginning to give public lectures, not only in Manchester, but in London, Birmingham, Rochdale, Macclesfield, and Liverpool. In May, 1842, he offered to read "A practical essay on the curative agency of neuro-hypnotism" to the Medical Section of the British Association, which was about to meet in Manchester. The essay was declined, but its author, who was not easily repressed, gave a conversazione at which he read the essay and demonstrated his cases to an audience which contained some distinguished men of science. Having convinced himself of the reality of the hypnotic state and of its therapeutic value, he deemed it his duty to make his results as widely known as possible. He was aware that this course was somewhat irregular, but he justified himself by the argument that only by demonstrating the safety and value of hypnotism could he win the confidence of the public and the co-operation of the profession.

In 1843 appeared Braid's chief work, "Neurypnology, or the Rationale of Nervous Sleep considered in relation to Animal Magnetism or Mesmerism, and illustrated by numerous cases of its successful Application in the Relief and Cure of Disease." The edition was soon sold, but the book was never reissued by its author. It was reprinted in 1899 along with some extracts from Braid's other works; but even this reprint is not now common. The word "hypnotism" was coined by Braid, and in this volume he explained what he meant by it, and by cognate words.

In the first part of the work he describes the phenomena of the hypnotic state, and details his mode of inducing it, and in the second part he gives an account of the patients whom he had treated hypnotically with more or less success. Many of the cases were suffering from various kinds of rheumatism or paralysis, but the list also includes deafmutism, failing vision, corneal opacity, and tic-douloureux as well as other ailments. He even hoped that hypnotism would benefit such conditions as tetanus and hydrophobia, the true nature of which was then obscure.

His other noteworthy publications were "The Power of the Mind over the Body" (1846); "Observations on Trance or Human Hybernation" (1850); "Electro-biological Phenomena" (1851); "Magic, Witchcraft, Animal Magnetism, Hypnotism and Electro-biology" (1852); "Hypnotic Therapeutics" (1853); "The Physiology of Fascination"; and lastly, "Observations on the Treatment of certain Forms of Paralysis," wherein he recounts his surgical operations on organic paralysis and his hypnotic treatment of the functional variety.

Braid was not, of course, the first to discover the hypnotic state, nor was he the first to assert that this state is wholly subjective, but he did reach that conclusion independently, and by dint of much experiment; and he also devised a simple means of producing hypnosis. His great merit lies in the fact that he stripped mesmerism of its occult and baseless extravagances, and reissued it in the form of hypnotism for the service of the physician and the psychologist. To Braid's work are directly attributable the subsequent developments of hypnotism in France and elsewhere. It is gratifying to recall that, while the Medical Section of the British Association rejected his essay in 1842, the report of the Hypnotic Committee of the British Medical Association issued in 1893 was such that it might have been written by Braid half a century before.

Braid's interests, however, were not confined to hypnotism. In 1858 David Livingstone complained that his explorations had been hindered by the tsetse fly disease among his beasts of burden. In February of that year Braid wrote to the *British Medical Journal* suggesting that Livingstone should try arsenic as a preventive and a remedy, since the snake charmers of India were said to employ it successfully against the poison of snake-bite. The Editor passed on the suggestion, and Livingstone later put it into practice. He was the first to do so, and thus the vogue of arsenic in the treatment of trypanosomiasis is directly due to this suggestion from Manchester.

Braid always remained a practising surgeon. In 1847 he performed Caesarean section on a woman who had been in labour for more than three days, and whose case was hopeless from the outset. He returned to the house a day or two later in the hope of performing a post-mortem examination, but even he must have been somewhat disconcerted when he found the funeral party already assembled. Nevertheless, he was not deflected from his purpose. He obtained permission to make an inspection of the body, "but," he

* Abstract of an address delivered to the History of Medicine Section at the Annual Meeting of the British Medical Association, Manchester, 1929.

complains, "we were necessarily compelled to be very circumspect as we were closely watched, and were thus prevented the opportunity of possessing ourselves of the pelvis. However, I had used the precaution of taking some plaster-of-Paris with us, and thus we were enabled to make an accurate model of the inlet of the pelvis." This model is duly figured in Radford's book on Caesarean section.

He took an active interest in sanitary matters. He volunteered for service during the cholera epidemic of 1832, and many years later he described in a letter to the press the awful conditions of the cellar dwellings in Manchester. He stated that the open gratings of the sewers were close to these dwellings and opened on a level with their floors. He advocated the use of proper traps, and suggested that the air from the sewers should be passed through fires before being allowed to escape into the atmosphere.

That he kept in touch with general science may be argued from the fact that in his later years he was honorary curator of the museum of the Manchester Natural History Society.

Personally Braid was a striking figure. His portrait in the Manchester Medical School confirms the impression of energy and self-assurance which his writings suggest. One suspects him to have been a Scot "with a good conceit of himself." Orthodox medicine in the city may have fought shy of him, but he certainly did not lack friends. Accounts of him speak of his high personal character, his jovial nature, and the warmth of his friendship. They add that by his death the poor of the city lost a good friend.

Is it too much to suggest that James Braid, take him for all in all, is by no means the least notable figure in the records of Manchester medicine?

JORDANBURN NERVE HOSPITAL.

OPENING OF THE LECTURE THEATRE.

THE Lord Provost, Sir Alexander Stevenson, presided over a large gathering, which included official representatives of the city, university, and Royal College of Physicians of [illegible] Thomas Holland, Principal [illegible] A. Fleming, President of [illegible] the Very Rev. Charles L. Warr, the Dean of the Thistle, Sir Robert Philip, Professor George M. Robertson, Sir Norman Walker, Professor Lorrain Smith, and the Members of Parliament for three of the Edinburgh divisions—when, on October 14th, the Right Hon. William Adamson, M.P., Secretary of State for Scotland, formally opened the new lecture theatre of the Jordanburn Nerve Hospital and Psychological Institute. This lecture theatre, of which some preliminary accounts have already appeared in our columns, has been built at a cost of £8,000, and it constitutes an additional wing to the hospital. In its design, the architects have taken every care that it should be suitable not only for ordinary academic purposes—for the classes of psychiatry in the university and in the Royal Colleges school of medicine, and for post-graduate and special courses of lectures on psychological and neurological subjects—but that it should be adapted to all the purposes of a theatre in which popular lectures of an educational character might be delivered. The authorities of the Jordanburn Nerve Hospital lay special stress upon this latter aim, for they believe that their object of preventing nervous disorder will be attained largely through the education of the lay public and the help of volunteers among laymen and lay-women. There are many volunteer societies whose co-operation will be welcomed, not only because their objects are allied with those of the hospital, but in acknowledgement of the spade work they have done for many years in creating a public opinion favourable to the ideals of mental hygiene.

ARCHITECTURE OF THE THEATRE.

The theatre holds over 250 persons comfortably. It has a sloping area, each row of seats being a foot higher than the one in front, so that everybody in the audience may have a perfect view of the platform, which is 12 ft. wide and 34 ft. long. Special attention has been directed to the lighting, and it will be possible, when lectures and demonstrations are given in the evening, for the audience to see clearly everything on the platform. These are features of importance, because it is intended to give from the platform clinical demonstrations of cases of mental disorder. The acoustics of the theatre are believed to be perfect; the ordinary speaking voice can be heard easily at any part of the hall, and there is no echo. These desirable ends have been attained by covering the walls and ceiling with a specially prepared porous material, by padding the backs of the seats with corduroy, so that there may be no echo from the wooden benches, and by covering the passages with matting. There is thus no surface from which the sound of the voice can recoil, except the wall behind the lecturer, which acts as a sounding-board. The theatre is furnished with [illegible] atus, and it is intended also shortly t [illegible] The lecture theatre is in the same [illegible] ent department, and its platform is in line with the hospital corridor; there is thus free communication between the theatre and the out-patient department, and patients in bed can, without inconvenience, be brought on to the platform. Communicating with the platform is a large ante-room, which may serve, among other purposes, as a waiting room for subjects of demonstration.

THE DEPARTMENT OF PSYCHOLOGY.

In recognition of the value of a study of pure psychology to clinical psychiatry a department of psychology, under the directorship of Dr. James Drever, Reader in Psychology at the University, has been instituted in connexion with the Jordanburn Nerve Hospital; Dr. Drever will be assisted by Dr. Mary Collins and Dr. Fairbairn. It may be noted that pure

JORDANBURN NERVE HOSPITAL: OUT-PATIENT DEPARTMENT AND LECTURE THEATRE.

psychology is a compulsory subject in the medical curriculum of Edinburgh University, and that it is taught on alternate days with the subjects of psychiatry and psychopathology during the whole of each spring term. It is intended ultimately, in connexion with the department of psychology, to build special laboratories for research purposes, but to achieve this end a sum of about £20,000 will be required.

SPEECHES AT THE OPENING CEREMONY.

At the opening ceremony the LORD PROVOST announced that an anonymous donor had, a few days previously, given a sum of £10,000 as an endowment fund for the working expenses of the lecture theatre and the out-patient department, and he expressed the hope that this lead might be followed by some other generous donor in Edinburgh. The SECRETARY FOR SCOTLAND, in declaring the theatre open, emphasized the importance to Edinburgh of having under one roof a hospital and out-patient clinic, a psychological institute, and a lecture theatre, all specially designed to tackle the problem of preventing and treating the nervous disturbances that were the forerunners of serious nervous breakdown. The prevention of disease, he said, whether of mind or body, was an economic proposition. It would pay the nation in pounds, shillings, and pence to provide facilities for this much-needed social service. He reminded the audience of the urgent financial needs of the laboratories—the vital centre from which the whole of the hospital's research activities must radiate. Principal Sir THOMAS HOLLAND said that Edinburgh, which had acquired its reputation largely because of its medical school, now had another opportunity, due in great part to the irresistible enthusiasm of Professor Robertson, of leading the medical schools of the world in opening up new ground in the field of mental disorder. Professor LORRAIN SMITH said that the Jordanburn Nerve Hospital would give medical students of Edinburgh an opportunity not only of learning the adopted,

recognized, and tested rules of treatment, but of following the working out of investigations upon which these rules were founded. The highest aim of a medical school was to turn out the greatest number of graduates possessing the habit of research. Dr. R. A. FLEMING stressed the contribution that psychology could make towards the solution of a number of problems, and said that he would suggest to the Secretary of State that in Borstal institutions they had problems which might be met most effectively by psychological methods. Mr. T. M. GARDINER, chairman of the board of managers, said that the novelty of their enterprise had aroused world-wide interest, and he paid a tribute to Professor Robertson, who, he said, had been the inspiration of the whole undertaking.

RESEARCH WORK IN MENTAL HOSPITALS.

REPORTS TO THE BOARD OF CONTROL.

THE increase in the amount of research work undertaken in the mental hospitals in England and Wales is largely due to the enlightened advocacy of the Board of Control, and is reflected in the ever-increasing size of each year's supplement to its annual reports. An account of Part I of the Board's fifteenth annual report appeared in our issue of October 5th (p. 629). The supplement in question is embodied in Part II of this report, and has just been published. It provides a convenient and succinct account, based on the reports issued by the individual mental hospitals, of the manner in which problems of psychiatrical diagnosis and treatment, and to a lesser extent of infective conditions incidental to institutional life, are being explored.

Treatment of General Paralysis.

As in previous supplements, considerable space is devoted to an account of the various methods adopted in the treatment of general paralysis, principally malarial therapy. The report from the West Riding Mental Hospital, Wadsley, Sheffield, by Dr. W. J. N. Vincent, medical superintendent, recounts that the malarial method of treatment has been carried out there for five years, and of the 140 cases treated during that time nearly 29 per cent. have been discharged and are reported to be doing well. The Lancashire Asylums Board report, furnished by Dr. G. A. Watson, pathologist to the board, refers to the following up of the malarial treatment in Lancaster Mental Hospital by courses of tryparsamide, by which means it is hoped that the improvement attained will be rendered more lasting. At Rainhill Mental Hospital the summary of conclusions regarding this mode of therapy is to the effect that malarial treatment alone is as effective as the combined therapy (malaria and tryparsamide) in producing a remission of the mental symptoms and changes in the serological reactions; that tryparsamide as an adjunct to malaria acts as a general physical tonic, allaying the motor restlessness, and thus making the subsequent nursing through the pyrexial attack less fraught with danger; that tryparsamide is apt to induce serious complications (chiefly visual and hepatic), and adequate safeguards and controls should be employed; and that if the word "cure" be defined as a complete remission of mental symptoms, serological changes, and accompanying physical signs, no case in their series can be said to be scientifically cured. Tryparsamide therapy is also the subject of one of the communications from the Maudsley Hospital. Dr. T. Tennant is of opinion that this is a most valuable drug in the treatment of general paralysis, but its action is aided by combining it with non-specific therapy, of which malaria has proved, in their series, safest. Beneficial results occur in indirect ratio to duration of symptoms. In early stages after treatment there is no parallelism between clinical and serological improvement. A partial parallelism exists in the later period, as all patients who show clinical improvement show a concomitant serological improvement.

In the report from the London County Mental Hospital, Bexley, communicated by Dr. G. Clarke, medical superintendent, is an account of extensive histological studies carried out by Dr. John Brander on patients who had died at various periods after treatment with malaria, and on patients who had not been so treated. The object of these studies was to ascertain the nature of changes induced by treatment, particularly to test the suggestion that malaria tends to transform so-called parenchymatous syphilis into ordinary tertiary disease of the brain and membranes; but it has not yet been possible to arrive at definite conclusions.

Included in the report by Dr. Golla on the research work done in the Central Laboratory of the London County Mental Hospitals are observations made on the histological changes in the brains of general paralytics treated by malaria, recurrent fever, and tryparsamide. The net result of these investigations has been to confirm previous work on the value of malarial therapy. The absence of spirochaetes in brains of general paralytics treated by malaria has been confirmed by numerous examinations.

Of the forty-four cases treated at the London County Mental Hospital, Horton (Dr. J. R. Lord, medical superintendent), all but four were by direct mosquito bite; 54.5 per cent. have definitely improved. A strain of quartan malaria was also obtained, and was employed in patients of a senile type who could not tolerate a full course of benign tertian. It would seem that quartan malaria can be used for a much more debilitated type of patient, and that the patients can withstand the fever for a longer time without showing any ill effects physically.

Dr. H. W. Eddison, medical superintendent at Wonford House Hospital, Exeter, contributes a report on the haematopoietic tissues in general paralysis. He considers that these changes serve to differentiate definite parctic cases from those suffering from other forms of cerebral syphilis. An analogy is drawn between general paralysis and pernicious anaemia in that there is, in both, impairment of the activity of the blood-forming organs, and the distribution of the degenerated areas in the medulla and cord is suggestively similar in both.

A report by Dr. A. A. W. Petrie, medical superintendent of the London County Mental Hospital, Banstead, on the treatment of general paralysis with relapsing fever, saprovitan, and milk injections, is of interest. With relapsing fever the percentage of improvements was a little lower than the general figures given for malaria. The results from saprovitan were disappointing. With regard to the milk therapy, Dr. Petrie is of opinion that the results are mainly due to the reaction to organisms which still remain in the fluid, and not to a protein reaction.

Dementia Praecox.

The pathology of dementia praecox, or, as it is now more generally termed, schizophrenia, has been investigated by Dr. Golla and his team of workers in the Central Laboratory, in continuance of work commenced in 1924. It has been found that in 84 per cent. of schizophrenic patients there exists a depression of the excitability of the respiratory centre closely resembling what occurs in normal sleep. The condition of these patients as regards the acid-base equilibrium was also in every way similar to that occurring in normal sleep.

Dr. Bamford of Rainhill Mental Hospital considers that there is a certain type of dementia praecox which runs a remarkably acute course, and generally terminates fatally in a few months. The digest of this paper, however, as it appears in the supplement to the Board of Control's report for 1928, does not make it clear whether any of the cases described might not be regarded as cases of acute toxic confusion with marked schizophrenic symptoms.

Three cases of dementia praecox were treated in the West Riding Mental Hospital, Wadsley, by induced malaria. One case of katatonic stupor of twelve months' unaltered duration began to show improvement shortly after the completion of the treatment, and subsequent progress has been satisfactory.

Toxic Infective Conditions.

The relation of infective processes to the causation of mental disorder has been widely investigated. Chief among these are the researches made by Dr. F. A. Pickworth and Dr. T. C. Graves with regard to the laboratory and clinical findings on patients in the Birmingham Mental Hospital. Dr. Graves draws attention to the prevalence of nasal sinusitis in the newly admitted cases, and points out that the symptoms usual in a normal

patient are not found in one mentally disordered. These symptoms frequently represent an extension of a chronic infective process which has been in existence long before the acute mental symptoms have arisen. In some cases the infective process has been traced back to an acute infective process such as measles, scarlet fever, etc.

The presence of diseased states of the nasal accessory sinuses among the Birmingham cases was reported for the year 1927 to be 25 per cent. of the direct admissions. Mr. Musgrave Woodman and Mr. Stirk Adams report the percentage of the 1928 admissions so affected as 33, and with bacteriological examination as a criterion the proportion of sinuses regarded as infected would be even greater than 33 per cent.

Miscellaneous Topics.

The report by Professor Shaw Bolton, medical director of the West Riding Mental Hospital, Wakefield, embodies the various papers and demonstrations which were presented at the annual meeting of the Royal Medico-Psychology Association held last year under his presidency.

Dr. Edwin Goodall's report from the Cardiff City Mental Hospital includes extensive research work on cholesterol and menstruation, and cholesterol and epilepsy, and on investigations into the hydrogen-ion concentration of the urine.

Among the publications by Dr. Edward Mapother, medical superintendent of the Maudsley Hospital, is one on "Early treatment of the psychoses and psychoneuroses," which appeared in our columns of August 18th, 1928 (p. 304). According to Dr. Mapother the ideal towards which to work is a special building designed for the reception of patients with every degree of mental disorder and for their proper classification. Whether such clinics are attached to the voluntary or municipal hospitals is, in his opinion, a minor point. Relatively small wards in general hospitals, staffed in the manner customary there, and psychiatric out-patient departments can only deal with a limited class, serving for routine treatment where the more adequate scheme is impracticable.

We have above referred to the fact that this supplement dealing with the scientific research work in mental hospitals is steadily growing in size. We hope it may soon be of such dimensions as to justify its publication as a separate volume. It might also, at some later date, be feasible for the subject matter to be grouped in accordance with the special type of investigations, and not as at present under the name of each mental hospital. This would ensure a wider knowledge and appreciation of such valuable research.

England and Wales.

Dinner to Dr. E. K. Le Fleming.

A DINNER was held at the Town Hall, Dorchester, on the evening of October 18th, St. Luke's Day, by the Dorset Local Medical and Panel Committee, in honour of Dr. and Mrs. E. Kaye Le Fleming of Wimborne. A large and representative gathering was present. The host and hostess were Dr. T. MacCarthy of Sherborne (chairman of the committee) and Mrs. MacCarthy. In addition to a large number of local doctors and their wives, the following were present: Sir James and Lady Brooks, the Rev. C. Canning (headmaster of Canford School) and Mrs. Canning, Mr. J. Leslie Torr (clerk to the Dorset County Council) and Mrs. Torr, Mr. S. S. Holloway (chairman of the Dorset Insurance Committee), Mr. R. J. Ganderton (vice-chairman) and Mrs. Ganderton, Dr. C. E. S. Flemming (Bradford-on-Avon), Dr. H. A. R. Unwin (chairman of the West Dorset Division) and Mrs. Unwin, Dr. G. C. Anderson (Deputy Medical Secretary) and Mrs. Anderson, Dr. O. Carter (honorary secretary of the Bournemouth Division) and Mrs. Carter. Apologies for absence were received from Major and Mrs. K. Balfour (chairman of the Medical Service Subcommittee), Dr. H. G. Dain (chairman of the Insurance Acts Committee), Major H. B. Nicholson, D.S.O. (chairman of the Health Committee, Dorset County Council), Dr. J. Elliott Robinson (county medical officer of health), Dr. C. J. Marsh (Yeovil), Dr. P. W. MacDonald (Weymouth), and Dr. O. Rees (Abbotsbury).

After dinner and the loyal toast, Dr. MacCarthy proposed the health of the principal guest. He said that they all knew Dr. Le Fleming as a man of astonishingly many parts, and the more they knew of him the more they were astonished that all those parts were so admirable; there was nothing shoddy about any of them. He was a renowned golfer, he was one of the founders of motoring in Dorset, and was a judge and connoisseur of antique furniture. They knew that as a doctor his scientific knowledge was of a very high order, widely appreciated in his neighbourhood, and that that was really his first love and his last love—his profession and the practice of it. As for Dr. Le Fleming's services to his colleagues the reason for the gathering that night was the work he had done, freely, all those years, for the honour and welfare of his own profession as a profession. Dr. Le Fleming felt he could never do enough for it to maintain its standard, and in whatever direction he had tried to uphold the honour of the medical profession he equally considered the duties of his profession to the public. He would never countenance anything which sacrificed the rights and welfare of the public—that was, the patients at large. First, there was the work he had done for the profession in general at the headquarters of the British Medical Association as a member of the Council, and as a member of the Insurance Acts Committee, and as chairman of the Panel Conference. At first Dr. Le Fleming worked for the profession locally, then he went to committees at headquarters and worked for the profession there. He had served for a great many years at a very great cost to himself of time and trouble and finance, but he reckoned it as nothing. Latterly he had added to their gratitude by becoming a member of the General Medical Council, which was the most important position in this country that a doctor could hope to attain. They were honoured and delighted that he had taken up that work, but sorry because it necessitated his giving up the work he had done locally. From 1912 to the present time he had been the head and front of the Panel Committee, under the National Insurance Act, in Dorset, and he had looked after the interests of doctors in Dorset. There were many conflicting interests to watch, but Dr. Le Fleming had always borne in mind that the honour of the profession must be maintained, and equally that the rights of insured persons must be maintained. Dr. MacCarthy then presented to Dr. Le Fleming, on behalf of the doctors of Dorset, a silver porringer of old Chinese design as a token of their esteem and as a slight recognition of his devoted services, and to Mrs. Le Fleming a silver clock. The toast was drunk with musical honours, and Dr. Le Fleming, in the course of his acknowledgement, spoke of the period of strain from which the medical profession of Dorset had now happily emerged. The strain would have been unbearable without the support he received from the whole profession, and more particularly from their chairman and Dr. Pridham. The three of them had had wonderful support in London from the Insurance Acts Committee, and in a special degree from Dr. Anderson and Dr. Dain. In conclusion, Dr. Le Fleming said that the work done by those who served on committees in organizing medical opinion brought its own reward; whatever services he himself had rendered were amply repaid by the friendships he had made. The toast of "The British Medical Association" was proposed by Dr. H. A. R. Unwin, who paid a tribute to the secretary, Dr. J. A. Pridham, and was responded to by Dr. G. C. Anderson. The health of the ladies was proposed by Dr. A. E. Staffurth, and that of the guests by Dr. G. Dru Drury, to which Dr. C. E. S. Flemming replied. The final toast was that of "The Chairman," proposed by Dr. H. M. Moyle.

London School of Hygiene and Tropical Medicine.

In the *Journal* of June 1st (p. 1018) a preliminary account was given of the course of study at the London School of Hygiene and Tropical Medicine for post-graduate students working for a diploma in public health. A programme, arranged by Professor Jameson, of special lectures, to be given in connexion with this course, has now

been issued. During the Michaelmas term Dr. J. S. Owens, superintendent of observations in the Department of Scientific and Industrial Research, and Professor Leonard Hill will lecture on atmospheric pollution; and Professor Hill will also lecture on sunlight and health, and clothing and climate. Mr. J. C. Dawes will give three lectures on the disposal of refuse. The programmes for the other terms of the academic year will include lectures on the control of the marketing of fish; shell-fish and the public health; anthrax and other diseases common to man and lower animals; public abattoirs; meat inspection; food poisoning; refrigeration problems; laws of inheritance; venereal disease; ante-natal hygiene; puerperal pyrexia and sepsis; mental hygiene; industrial hygiene; school hygiene; town planning; port sanitation; and international hygiene. The programme, as will be seen, is an interesting one, and is an indication of the very high standard of training that the school aims at giving to students working for the diploma of public health. We are informed that the number of students taking the course is far greater than was expected by the director and the school council, but members of the public health services and other interested members of the general public will be admitted to these lectures.

Memorial to Dr. B. H. Mumby.

The Bishop of Portsmouth dedicated, on St. Luke's Day, October 18th, a window at St. James's Church, Milton, to the memory of Dr. B. H. Mumby, who died in 1914. Dr. Mumby, who was formerly medical officer of health for Portsmouth, and, later, medical superintendent of the borough mental hospital, was at one time a member of the Council of the British Medical Association, and had been secretary and chairman of the Portsmouth Division. The memorial took the form of a stained glass centre panel in a window in the north wall of St. James's Church, the figure represented being that of St. Luke; below the window a brass tablet has been placed, upon which is inscribed. "This window, in memory of Bonner Harris Mumby, M.D., D.P.H., V.D., was given by members of the Portsmouth Medical Association, 1929." The window was designed by Mr. Cuthbert Atcherley, and was executed by Messrs. Wippell and Son of Exeter; it was unveiled by Drs. H. Warren and Philip Green. In his address the Bishop remarked that it was the memory of a beloved physician which brought them together. The Gospel of St. Luke and the Acts of the Apostles were in the front rank of the writings of the ancient world as regards accuracy, importance, and authenticity. The close connexion of the well-being of the mind and body was a theme which ran through St. Luke's Gospel, and it was clear that the author had been impressed by the discoveries he made in tracing accurately the facts that happened, for his writings recorded the triumph of spiritual forces over physical and material conditions. The memorial window, added the Bishop, commemorated the service rendered to the community by a man whom the inhabitants of Portsmouth knew to have been devoted to his work and swift to recognize the great part played by environment in human well-being. Dr. Mumby had spent his life not only in healing the sick, but also in reconstructing conditions of life in the town to prevent disease and to further physical welfare. He had worn himself out in striving to improve the environment of the people and to promote systematic organization and reconstruction of the conditions in which they lived. The Bishop eulogized the great services rendered by the medical profession, and added that without progressive healing of the sick and the conquering of disease the Kingdom of God could never come in this or in any other world. Before the close of the service the congregation were asked to remember certain medical practitioners who had died within recent times, including Mr. Charles P. Childe, Dr. V. J. Lane, and Dr. J. Lister Wright. An offertory, which was taken for medical charities, realized more than £16; the church was crowded, and extra chairs had to be provided. Many of the medical practitioners who were present wore their academic robes, and a processsion was formed. It is hoped that the service on St. Luke's Day will become an annual event in Portsmouth.

Holloway Sanatorium.

The governors of the Holloway Sanatorium at Virginia Water have now provided a nurses' home in the hospital grounds, with admirable accommodation for some seventy-five of the female nursing staff. The opening ceremony took place on Saturday, October 19th, after a luncheon party in the recreation hall of the main building, presided over by Sir Lindsey Smith, chairman of the Board of Governors. The company, as was only natural, included many who are prominently associated with psychiatry and the care of mental patients. Among those present were Sir Robert Armstrong-Jones and Dr. Nathan Raw (Lord Chancellors' Visitors in Lunacy); Mr. L. G. Brock (chairman of the Board of Control), Sir Hubert Bond, Mr. Fraser Macleod, K.C., and Mrs. E. F. Pinsent (Commissioners of the Board of Control); the Right Hon. J. S. Sandars, the Bishop of Guildford, the Earl of Lucan, Viscount Fitzalan, and other governors of the Holloway Sanatorium; General Sir Edmond Elles and the Hon. Arthur Brodrick (trustees), and Dr. Henry Devine (medical superintendent). The formal opening took place in a marquee outside the new building. The Bishop of Guildford pronounced a prayer of dedication, and a hymn was sung by the choir of hospital nurses and attendants. Sir Lindsey Smith, before inviting the Countess of Midleton to unlock the main door and declare the home open, paid a tribute to those who had worked hard in this good cause, and spoke of the need of proper accommodation and amenities for those who devoted themselves to nursing the mentally afflicted. After performing the ceremony Lady Midleton acknowledged briefly a vote of thanks, and expressed her deep interest in all that concerned the welfare of hospital nurses throughout the county of Surrey.

Scotland.

Retirement of the Principal of Glasgow University.

At a meeting of the University Court of Glasgow University on October 10th, Sir Donald MacAlister, who presided, formally intimated his intention to resign office on October 15th. The court accepted the resignation with regret, and Lord Provost Sir David Mason, speaking on behalf of the city of Glasgow, said that for twenty-three years of tenure of office as principal, Sir Donald MacAlister had been a wonderful administrator. He considered that a tribute to the great confidence which Sir Donald MacAlister's administration had spread abroad was to be found in the large number of chairs that had been endowed, and in the high place now occupied by Glasgow University. At the same meeting, intimation was made of a gift of £20,000 by an anonymous donor for the foundation of two or more scholarships in memory of Dr. David Foulis and Mr. Stuart Foulis. Intimation was also made that the Lord Rector, Mr. Stanley Baldwin, would come to Glasgow early next year for the purpose of delivering his rectorial address. On October 15th Sir Donald MacAlister delivered a valedictory address to the students of Glasgow University in the Union Hall.

Post-Graduate Courses in Glasgow.

The Glasgow Post-Graduate Medical Association has arranged a programme of special courses and demonstrations during the winter months on the lines of those which have proved popular in recent years. A series of demonstrations on Wednesday afternoons will continue from November 6th until May 28th, 1930, and include medicine, surgery, obstetrics, and certain special subjects, thus enabling practitioners to make themselves acquainted with recent advances as regards diagnosis and treatment. The fee for this course is three guineas. Slit-lamp classes for ophthalmic surgeons will be arranged during November and December at the Glasgow Eye Infirmary on days and hours to suit the convenience of those participating. From January until May there will also be a course of instruction qualifying for the diploma in ophthalmic medicine and surgery of the Conjoint Board in England. Particulars of these ophthalmological courses may be obtained on application to the medical superintendent of the Eye Infirmary,

Berkeley Street, Glasgow. Special facilities are offered at the Royal Maternity and Women's Hospital, Glasgow, for the study of clinical obstetrics, including ante-natal work; for details of these application should be made to the house superintendent of this hospital. A series of demonstrations on diseases of the ear, nose, and throat will be given on Tuesday and Thursday evenings from the middle of April, 1930, to the middle of May, at the Ear, Nose, and Throat Hospital, St. Vincent Street. A limited number of clinical assistantships are available during the winter months at most of the institutions which are associated with the work of the Post-Graduate Medical Association. Graduates desiring to obtain one of these assistantships are recommended to enrol for a period of three months, and be prepared to devote to the work either the whole or part of the day according to the terms of the particular assistantship. Further information in this respect may be obtained from the secretary of the Post-Graduate Medical Association, Dr. James Carslaw, 9, Woodside Terrace, Glasgow, C.3.

Royal Medical Society of Edinburgh.

The inaugural address of the Royal Medical Society for the one hundred and ninety-third session was given in the Society's Hall on October 18th. Mr. C. W. Cathcart, F.R.C.S., delivered the address, and dealt particularly with the personality of the late Dr. Joseph Bell, the original of Sir Arthur Conan Doyle's character of Sherlock Holmes. He told several anecdotes which illustrated Dr. Bell's great power of obtaining information by inference drawn from a patient's accent, or some apparently trivial detail in dress or person. One young man had been surprised when Dr. Bell remarked to him that he had walked along the Meadows on his way to the Infirmary. Dr. Bell explained that when driving through the Meadows he had noticed a heap of bright red clay, which had been taken from a quarry at a distance, and there was no other bed of red clay anywhere near resembling that to be seen upon the patient's boots. In another case he had deduced that a man was a mason from observing the callosities of the man's left forefinger and thumb, caused by the firmly held and hammered chisel. Mr. Cathcart mentioned several important discoveries which had resulted from thoughtful observation. Thus, Edward Jenner, while an apprentice, had been struck by the remark of a woman who said that she could not take small-pox because she had had cow-pox. After investigation among other milkers, he had carried out experiments of inoculating with cow-pox, and afterwards with small-pox, to which he discovered that patients had then become immune. The discovery of the anaesthetic effects of nitrous oxide gas was accidentally made by Dr. Wells of Boston, who, in 1844, had noticed that a man excited by the inhalation of this gas knocked his legs on the benches near him without seeming to feel any pain. Hypodermic injection as a substitute for oral administration had been discovered by Dr. Alexander Wood in 1853, by what might be called an accident. He had a patient much troubled with neuralgia, and, hoping to relieve the pain, he injected a few drops of morphine solution at the place. Next forenoon, when he called on the patient, he found her soundly asleep, and realized that the solution had been absorbed into the circulation and was thus capable of producing a general effect.

Midlothian Nursing Services.

The annual meeting of the Midlothian County Nursing Association was held on October 7th in the County Chambers, Edinburgh. Lady Elphinstone, president of the association, presided, and the principal speaker was Dr. J. Parlane Kinloch, chief medical officer of the Department of Health for Scotland. Lady Elphinstone stated that there was a pressing need for the establishment of a nursing service to cover the entire county, as there were still several villages without nurses. The committee proposed to undertake, in addition to nursing, the public health and child welfare work. During 1928 the nurses in the county had paid over 83,000 visits, and had attended 338 maternity cases. Dr. Parlane Kinloch remarked that the whole position had to be reviewed in the light of the Local Government (Scotland) Act of 1929. The doctor could not do his work without the nurse, and in any organized health service it was necessary to have an organized nursing service. The speaker believed that a reorganization of the training of nurses was wanted, for at present any woman who made a comprehensive profession of nursing required ten years of tutelage, including three or four years general training, three years fever training, one year maternity nursing, one year of mental diseases, and so on. This state of affairs was ridiculous, and he looked forward to a time when, in a period of four or five years, a woman going in for nursing could get a comprehensive training in all its branches. The speaker aimed at the orientation of the county services of Scotland round the medical schools of Edinburgh, Glasgow, Dundee, and Aberdeen, which would give the utmost efficiency with reasonable economy. The nursing service at present was unbalanced, being good in some places, not so good in others, and absent in still others, and it was not linked up with institutional treatment. The national health insurance system was breaking down at the vital point where the person needed nursing and hospital treatment. A combination of the voluntary and official organizations in the country was necessary, and the five regional committees now spoke with one voice for Scotland, and had a liaison committee which would speak to the Secretary of State with the voice of the voluntary hospitals. When they knew what the voluntary system could do, they would go to the local authorities and ask them to fill the gap. The same thing held good as regarded the nursing service, and he looked to Edinburgh and Midlothian to formulate a scheme which would be a model for the whole of Scotland and for the whole world.

Compulsory Treatment of Venereal Disease.

A conference of representatives of local authorities, held under the auspices of the Scottish committee of the British Social Hygiene Council, was held in the City Chambers, Glasgow, on October 18th. The Edinburgh proposals in regard to dealing with this type of disease and with the problem of the defaulter in treatment, were outlined by Mr. A. Grierson, town clerk of Edinburgh. He said that the Edinburgh corporation had come to the conclusion that these diseases would never be controlled by a purely voluntary scheme, because it had been found, all over the country, that there was a considerable percentage of infected persons for whom peaceful persuasion in regard to treatment was of no avail. A review of the work accomplished recently in Scotland was given by Dr. David Lees of the Edinburgh Royal Infirmary, who said that the annual cost of administration of the Venereal Diseases Regulations in Scotland varied from £60,000 to £78,000, one-quarter of which was paid by the local authorities. Dr. T. F. Dewar, of the Department of Health for Scotland, gave an account of the administrative control, and the need for further powers of control was emphasized by Dr. A. S. M. Macgregor, medical officer of health for Glasgow. At the conclusion of the meeting a resolution was submitted by Bailie Dunlop, and carried unanimously, that the conference was of opinion that the condition of affairs anticipated by the Trevethin Committee in 1923 had now emerged, that the time was ripe for applying greater measures of control, that the action already taken by the corporations of Edinburgh and Glasgow and other local authorities was worthy of approval, and that these bodies should be urged to continue their efforts to obtain from Parliament additional powers for the control and treatment of persons suffering from venereal disease.

St. Andrews Ambulance Association.

A general meeting of St. Andrews Ambulance Association was held in Glasgow on October 10th. The Duke of Buccleuch presided. It was stated that during the past year 33,199 calls had been made upon the association's ambulance wagons. It was specially pointed out that, during the past year, 1,475 cases of accident in which motor vehicles were involved had been attended, and that this was an increase of 180 over the number in the previous year. The chairman, in moving the adoption of the report, said that this was the first annual meeting which had been held in the new headquarters of the

association, and it was a matter of congratulation that the sum required to complete the building scheme had now been fully subscribed. The association had some fifty local centres, covering the whole of Scotland, and during the past year the wagons of the association had attended over 33,000 cases of accident alone. The association had now been in existence for forty-seven years.

Fifty Years in Medical Practice.

On October 15th, Dr. James Hunter, Linlithgow, was presented with his portrait in recognition of his long public service to the community of Linlithgow. Mr. James Forbes presided, and Provost Meek, who made the presentation, remarked that Dr. Hunter had practised for fifty years in the burgh, and during that time had used his skill for the alleviation of suffering among rich and poor alike. The speaker pointed out that of Dr. Hunter's family, four were members of the medical profession, one being a well-known practitioner in Dumfries, while his brother, Dr. Joseph Hunter, M.P., was the Scottish Liberal whip. Mrs. Hunter was at the same time presented with a silver salver. The portrait is the work of Mr. Henry W. Kerr, R.S.A.

Ireland.

Vital Statistics of the Irish Free State.

THE Registrar-General's weekly returns of deaths in the Dublin registration area and the principal provincial urban areas for last week and the past four weeks respectively were equal to the following annual rates per 1,000 of the population: Eleven town districts, 12.9 and 12.7; Dublin registration area, 12.4 and 12.1; Dublin county borough, 13.0 and 12.6; Cork, 15.9 and 17.1; Limerick, 11.9 and 14.5; Waterford, 11.7 and 13.2. The deaths from the principal epidemic diseases for the eleven town districts were equal to an annual rate of 1.4 per 1,000. In the Dublin registration area the births registered during the week numbered 256 (142 boys and 114 girls) and the deaths 124 (50 males and 74 females). The deaths registered (omitting the 23 of persons admitted to public institutions from outside the area) represented an annual rate of 12.4 per 1,000 of the population. During the thirty-nine weeks ended with September 28th the death rate averaged 16.3, and was 0.8 below the mean rate for the corresponding period of the ten years 1919–28.

Health of Belfast.

In his annual report on the health of Belfast for the past year Dr. Samuel Barron, acting medical superintendent officer of health, states that the birth rate was 22.5 per 1,000 of the population, a decrease of 0.4, and the death rate 14 per 1,000, an increase of 0.4. The number of cases of infectious diseases reported during the year was 2,717, an increase of 813 on the previous year's figure. This was largely due to an increase in scarlet fever cases, and also in typhoid and paratyphoid fever cases. The incidence of diphtheria was high, and 628 cases were notified during the year. In the same period 446 persons died from cancer, and 63 from influenza, while 123 persons died from violence. There were 260 deaths of children under one year, an infantile mortality rate of 103 deaths per 1,000 births registered. In the preceding year the number registered was 961, corresponding to a rate of 101 per 1,000 births; the rate for 107 English cities is 70. Dr. Barron hopes that measures for preventing such unnecessary waste of infant life will be adopted.

The report by the medical officer of health for the county borough of Belfast for the year 1928 includes reports by the chief tuberculosis officer, the visiting surgeon of the municipal hospital for tuberculosis, and of the medical superintendent of the municipal sanatorium, Whiteabbey. Dr. Andrew Trimble, the chief tuberculosis officer, comments on the part played by unemployment and the consequent poverty in fostering the spread of tuberculosis. The death rate in the city in 1928 from pulmonary tuberculosis has decreased by over 40 per cent. as compared with that of 1914; the corresponding reduction in the rate for non-pulmonary tuberculosis was more than 62 per cent. For every 100 persons who died of pulmonary tuberculosis in Belfast in 1918, only 47 died in 1928—a reduction in the rate of 53 per cent. Dr. Trimble urges the importance of arranging for more intensive education of the community in matters of public and personal health, and in the prevention and cure of tuberculosis. He asks for more open-air schools for delicate children, and for children in danger of developing tuberculosis through living in unhealthy home surroundings. He recommends the addition to the medical curriculum of a course comprising the history, prevention, diagnosis, and methods of treatment of tuberculosis, and the means of dealing with it in the community. He mentions that consideration is being given to increasing the accommodation for the treatment of non-pulmonary tuberculosis in children. He repeats his plea of last year for the extension of medical benefit to insured persons in Northern Ireland on the lines existing in Great Britain, and mentions the need of a larger medical staff. Mr. H. P. Malcolm, visiting surgeon to the municipal hospital for tuberculous children, which has been in existence for nearly eight years, states that the present accommodation is quite inadequate; treatment by ultra-violet light is impracticable owing to the absence of electricity. The present custom of sending patients to the central institute for *x*-ray examination is not satisfactory. Dr. P. S. Walker, medical superintendent of the municipal sanatorium, complains of the regrettable delay in instituting active remedial measures; patients are still reaching the sanatorium in many cases too late for effective treatment. The accommodation there also is said to be inadequate, and in some respects unsatisfactory, but there has been a gratifying reduction in the number of deaths; it is feared, however, that this will not be the case in the current year. Plans have been adopted for an open-air school attached to the sanatorium at a cost of about £1,800; this will replace an existing school building which has proved to be inadequate, particularly during inclement weather.

Correspondence.

THE RACIAL INCIDENCE OF DISEASE.

SIR,—Periodically we are told that this or that human race is more afflicted by this or that non-bacterial disease (for example, cancer or adenoids) than this or that other race. Like most anthropological data (for example, cephalic indices) these "facts" are invariably empirical. Cause and effect are not traced. Moreover, they are always disputed—partly because they are empirical and partly because they depend on limited personal experience. When we are able to link cause with effect we receive an assurance of truth much stronger than mere enumeration can supply. A seeming truth then becomes a necessary truth.

Bacterial diseases cause enormously more mortality and suffering than the non-bacterial maladies. Here cause and effect can be traced with the utmost clearness. The manner in which races have differentiated is plainly indicated. The following is a law to which there is no exception. "Every human race is resistant to every lethal and prevalent human disease precisely in proportion to the length and severity of its past experience of that disease." The same is true of brutes and plants and their diseases. Thus Englishmen are more resistant to tuberculosis than African blacks, who are more resistant to malaria; and the native herbivora of East Africa are more resistant to the fly disease than imported stock. In England we are especially resistant to the diseases of civilization (the crowd diseases). We think England healthy. It is perhaps the most deadly region in all the world for the aborigines of half the world. A black from African forests, or a Red Indian, or a Polynesian who attempts to reside in London perishes more surely than an Englishman who tries to live under native conditions in the forests of the Congo or the Amazon. This fact is vaguely known, and for that reason we seldom see even such seafaring types as the Kanakas.

Why are races particularly resistant to the diseases of which their ancestry has had much experience? Consider tuberculosis: (1) It is a disease of crowds, especially those

which inhabit the dark and ill-ventilated dwellings of northern climates. (2) It is chronic; that is, individual experience of it weakens rather than strengthens powers of resistance, and therefore it is of indefinite duration; the individual (not the race) cannot become immune, or "acclimatized," to it. (3) In England its bacteria are so prevalent that probably no one escapes illness unless naturally immune, or death unless highly resistant. (4) Individuals vary in powers of resistance; some do not contract the disease even in the slums of great northern cities; some recover more or less quickly, some perish slowly, some are so unresistant that they perish swiftly. (5) Powers of resistance tend to run in families; that is, they are inheritable; this is best seen when we compare individuals of different races—for example, Polynesians and Englishmen.

If individuals vary in their powers of resisting tuberculosis, if these variations tend to be transmitted to their descendants, and if tubercle bacilli choose for death the more susceptible, and for life the more resistant, then this is that natural selection which "shook the thought of the civilized world" nearly three-quarters of a century ago, which a majority of naturalists accepts on grounds of common sense, but which a minority rejects because "no man has seen natural selection at work." Naturalists suppose that "man has escaped from natural selection." "There is no veil like the veil of familiarity." We are unable to perceive natural selection among wild animals and plants because we cannot observe closely enough the vital variations of individuals or watch their careers from birth to death. But natural selection among men is as manifest as that artificial selection which has created our domesticated animals and cultivated plants. Its results also are manifest; for, as I say, every race is resistant to every lethal and prevalent disease in proportion to the length and severity of its past experience of that disease. When diseases are not prevalent or not lethal (for example, common cold and chicken-pox) then ancestral experience does not increase powers of resistance.

We deal here with matters of more than academic interest. The social and political consequences are tremendous. Natural evolution is very slow. Here we have forces enormous, uncontrolled, uncontrollable, unrecognized, working towards immense conclusions. No race can become civilized which has not evolved *gradually* against the crowd diseases. Man and his diseases appear to have originated at a very remote period in the eastern hemisphere. When Columbus broke the age-long isolation between the East and the West he took with him not only men highly resistant to the Old World diseases, but also the diseases themselves. Then began the greatest tragedy in human history. The races of half the world commenced to displace those of the other half. The New World began to be swept by immensely destructive epidemics. Small-pox, measles, whooping-cough, and the like, piled the earth with the dead. When all were stricken, famine followed. Whole tribes were exterminated. The work of tuberculosis, though slower, was more thorough. It came not like air-borne disease as a swiftly spreading epidemic, but when it came it stayed, and exterminated.

The Spanish and Portuguese, then powerful maritime nations and first in the field, elbowed the British and French to the seemingly inhospitable North. But the forests of the South were defended by malaria, which rendered true colonization difficult. Such colonization as there was had to be accomplished by means of negro slaves. But North America was unprotected, and into the vast void created by imported disease the British and French poured. The former won the battle of *Quebec; French* immigration ceased; and all the North fell into the grasp of the Anglo-Saxon, giving their race almost illimitable room for expansion, and finally establishing it as the greatest on earth. Quite unconsciously and almost peacefully the process continues in Australasia and Polynesia.

The British hold conquests in the East, where their wars have been more bloody than in the West. But they have introduced no new diseases and the natives multiply. If history teaches any truth with certainty, it is that conquest is never permanent without the extermination of the aborigines. Thus the Romans, who conquered but did not destroy, have gone from Britain, and the Normans are absorbed. But the descendants of the Saxons, who exterminated, still inherit the land. British conquests in the West, with the natives gone, with foundations dug deep by bacteria, are apparently as permanent as the hills; for civilized peoples do not exterminate with the sword, and diseases have reached their limits. But all precedent indicates that their conquests in the East are only temporary.

Is it not remarkable how the significance of these monstrous events has escaped the attention of the learned concerned—medical men, naturalists, anthropologists, historians? There is no veil like the veil of the excessively obvious.—I am, etc.,

Southsea, Oct. 20th. G. Archdall Reid.

Sir,—In reply to my letter in the *Journal* of September 14th (p. 518) criticizing the unconvincing evidence on which far-reaching conclusions as to the racial incidence of disease are being based, Dr. J. S. Mackintosh on October 5th (p. 647) advances arguments of the *a priori* type as to why Jews should be prone to adenoids and other catarrhal affections. However interesting his arguments are they do not constitute facts; indeed, Dr. Mackintosh can only fall back on his own impressions, derived in practice, which are not synonymous with established observations. In advancing arguments why Jews in this country should be excessively prone to adenoids among other catarrhal affections, he points out that to the Jews, as a race which has evolved in a warm climate, the climate of England is severe. Apart from entering upon the very debatable ground as to whether the modern Jew is anything but a European, Dr. Mackintosh begs the question by assuming that a race from a warm climate will be prone to respiratory catarrh if transferred to a colder region. But surely there is no evidence for such a contention. Is there any evidence that Italians in New York suffer excessively from respiratory catarrh, and particularly from adenoids? If adenoids are all a matter of disharmony between race and climate one would expect that the Welsh would be more prone to this affection than the English, the Welsh being of Iberian origin, cradled in a warm climate, and the English coming essentially from a hardier stock—Saxon, Dane, and Norman. But apart from all these arguments, which lead nowhere, what is the evidence that adenoids are the result of respiratory irritation? Unfortunately these masses of lymphoid tissue present a problem which is not quite so simple.

Dr. Mackintosh's argument of the proneness of Jews to catarrhal troubles is reminiscent of the old argument of the racial predisposition of Jews to trachoma. The Jews were smitten with trachoma because their conjunctiva was ill adapted to the climatic conditions under which they lived. Altogether, trachoma was the expression of an unsuitable climatic environment; it was thus that any and every climate was in turn blamed for trachoma. No one now believes in the climatic origin of trachoma, and the racial predisposition of Jews to trachoma has followed other "Jewish" diseases into oblivion.

There is a tendency to regard disease not as an entity in itself but as the expression of disturbed harmony between the individual and his environment, both external and internal. In such a view of disease the interaction between the racial and environmental factors is of obvious importance, and it is therefore all the more imperative to distinguish between fact and hypothesis. In this barely explored field an ounce of fact is worth more than a ton of theory, even of the most ingenious quality.—I am, etc.,

London, W.1, Oct. 7th. M. Sourasky.

TONSIL AND ADENOID OPERATIONS IN HOSPITAL PRACTICE.

Sir,—Why should Mr. Arnold Jones (October 19th, p. 736) assert that "any action taken by the profession in this matter . . . would be premature" pending the results of his investigations? It is the almost unanimous opinion that abolition of "out-patient" tonsil operations is a reform long overdue. A wide correspondence in your columns in 1920–21 condemned the practice. In 1922 the

Section of Laryngology of the Royal Society of Medicine published a resolution[1] of which the apposite clause (quoted by Dr. P. Watson-Williams in your issue of September 28th, p. 599) is identical with the resolution *unanimously* adopted by the Children's Section last July at Manchester.

Nine years ago you published my statistical evidence[2] of the greater risks run by "out-patient" *opérés*. While assistant surgeon to the throat department of the Royal Infirmary I performed about 400 tonsil operations annually. Despite the precautions advised by Mr. Arnold Jones—which, by the way, have long been universal practice—each year brought confirmatory evidence. Since I have been in charge of that department every child has been admitted, though it is still doubtful whether the reform can be maintained. Admission to hospital for forty-eight hours after operation spares the parents the most difficult part of the nursing—a point of real importance in poor homes—and tides the children over the period when risks from chill or infection are greatest. Mr. Arnold Jones said at Manchester, "The surgeon may be called upon to deal with haemorrhage more or less severe a few hours after operation." And what if this occurs at night in a poor home three or four miles away? He himself admits to hospital (*a*) children from a distance, (*b*) apparently all delicate or sickly children, (*c*) "older children," (*d*) those with bad homes, (*e*) those unfit to return home. It is simply misleading to allege that the *extra* cost of admitting the remainder would be "vast." Each cot can deal with about 130 cases a year, and the patients need no expensive treatment during their short stay.

It rests with hospital governors to say what provision shall be made for those attending their institutions, and it has long been their boast that they afford the poorest as good treatment as the wealthiest can obtain. Yet no medical man would wish to submit his own child or the child of a private patient to "out-patient T's and A's." As long as medical heads of throat clinics acquiesce in "out-patient" operations, reform will lag. The most conservative opponent of change can hardly regard them as desirable. His only argument is "*faute de mieux*—an out-patient operation is better than nothing at all." Agreed, but do not let us confuse the issue.—I am, etc.,

E. Watson-Williams.

Clifton, Bristol, Oct. 19th.

RADIUM IN SURGERY.

Sir,—In his letter in the *Journal* of October 19th (p. 737) Mr. Souttar states that we must depend upon results and not upon theoretical considerations for an estimate of the value of radium, and therefore I suggest that it would be best to forget the physicist's division of rays into alpha, beta, and gamma, and only regard them as irritating and non-irritating. He appears to be impressed with the fact that 0.6 mm. platinum absorbs practically all the primary beta rays, and is not aware that the softer gamma rays are as destructive as the harder beta rays, and in order to cut off the former a thickness of at least 1.0 mm. of platinum is necessary. The increase of platinum from 0.6 to 1.0 mm. is only futile in theory; in clinical gynaecological practice it is established beyond question, and for experimental evidence on this point Mr. Souttar might refer to a paper published by Lazarus-Barlow as long ago as 1914. Again, he appears to forget that the secondary radiations (rays of Sagnac) are efficiently absorbed by rubber tubing 3.0 mm. thick. Mr. Souttar is perhaps entitled to argue that the numerous discrete burns he must produce by his technique are not prejudicial to the treatment; time alone can answer this proposition, but that burns are produced is beyond question. Finally, Mr. Souttar speaks with confidence of the immediate results in carcinoma of oesophagus and breast. May I recall that twenty-five years ago workers were similarly expressing themselves about immediate results, and three or four years later radium treatment was almost abandoned. I would suggest to all workers with radium that it would be wise to avoid publishing results until five years have elapsed from the treatment, by which time the space they will require will be very much reduced.—I am, etc.,

Sidney Forsdike.

London, W.1, Oct. 21st.

LYMPH-STASIS AND CANCER.

Sir,—In Mr. Sampson Handley's address entitled "Lymph-stasis the precursor of cancer" (October 5th, p. 607), he points out that Warburg has shown that cancer cells differ in metabolism from ordinary cells; but, Mr. Handley says, "... no suggestion has hitherto been offered as to the way in which this change of cell habit is brought about." I wish to say that this matter was fully dealt with in my book published in 1927.[1] As regards lymph-stasis, this cannot be regarded as the precursor of cancer, as lymph-stasis itself depends upon important precedent causes. Moreover, if it is necessary to be in action for twenty to thirty years, as Mr. Handley estimates, this would rule out cancers occurring before, say, 25 years of age. A serious error, I submit, is to allot no role in cancer production to the nervous system, which, directly or indirectly, controls the whole of the body tissues and their activities. Neither can it be at all useful to compare vertebrate cells with amoebae. Cancer only occurs in vertebrates, which have a highly organized nervous system of a particular kind. Amoebae possess no nervous system. Vertebrate cells are civilized and have established law and order imposed or, at any rate, enforced by the nervous system. Amoebae, like primitive man, have merely the law of self-preservation. Therefore, to produce a four-celled organism from a one-celled one, or vice versa, if that were possible, would, I contend, teach us nothing. Anarchists, in civilized communities, or in vertebrate cell groups, are produced by a partial breakdown or misapplication of "the law," and they are also "exterminated," or brought under control, in both these situations, if and when "the law" resumes its normal sway.

I cannot agree with Mr. Handley that cancer occurring in a case of elephantiasis is a good example of lymph-stasis being the precursor of cancer. In my opinion body-poisoning, chronic irritation, and local anaphylaxis are the precursors of cancer, and these would appear to be present in elephantiasis. The case he quotes of elephantiasis of the leg rapidly becoming cancerous under radiant heat treatment supports this view. A further criticism of the lymph-stasis precursor theory lies in the fact that no individual epithelial or connective tissue cells are ever exposed to lymph-stasis action for anything like twenty to thirty years, owing to waste and repair of tissues. Mr. Handley's mention of the tuberculous families, subject to multiple papillomata of the large bowel, and his reference to mice being more subject to cancer after injection of tubercle bacilli, simply confirm the views expressed in my book. Tar-cancer experiments, which are mentioned by Mr. Handley, I have previously shown to be fallacious, and I venture to assert that no amount of "short-cuts" by animal experimentation, tissue culture, or what not, will ever succeed in demonstrating the cancer process or in obtaining an understanding of it. It is difficult to understand how Mr. Handley can claim that lymph-stasis "lies at the root" of sarcoma also, if we bear in mind his dictum that twenty to thirty years is necessary for lymph-stasis to produce "cancer." Possibly he exempts sarcoma from this condition. At any rate, I know of cases where the initiation, course, and fatal termination of sarcoma following injury were a matter of months, not years.

I submit that Mr. Handley's "proofs that lymph-stasis lies at the root of cancer—certainly of carcinoma, possibly of sarcoma," cannot be admitted as such. As regards the role of lymph-stasis in such cases, one can, I think, only regard it as a natural concomitant of the far more important precedent conditions present in the initiatory stages of tumour (and cancer) formation.—I am, etc.,

TREATMENT OF INFECTIONS WITH S.U.P. 36.

SIR,—I was much interested in the article by Dr. R. M. Pearce on the use of Mr. McDonagh's S.U.P. 36 in influenza. I have used the drug for over two years; I have not found it superior to other remedies in septic conditions, such as boils, quinsy, tonsillitis, etc., but in catarrhal fevers it is invaluable. Dosage need not be considered so carefully; I have injected 1 c.cm. into infants 1 year old.

The following are a few striking cases:

1. (?) *Pneumonia.*—A married woman, whose confinement was overdue, had a rigor, and the temperature rose to 104°. There was pleuritic pain at the right base, rapid breathing, and suggestive signs of deficient air entry at the right base. The same evening the temperature was 102°, and 1 c.cm. of S.U.P. 36 was injected. The temperature fell continuously from the moment of injection, and was subnormal in twenty-four hours. Labour began during this period, and was normal, as was the puerperium.

2. *Diaphragmatic Pleurisy.*—A boy, aged 6, had a rigor, and his temperature rose to 101°; there was rapid, painful breathing, and abdominal rigidity on the right side. Sodium salicylate was given, but a restless night followed. Next day the temperature was 102°, and, thirty-six hours from the commencement of illness, I injected 1 c.cm. of S.U.P. 36; the following night was the most comfortable for three weeks, and next day the temperature was normal, though on the following day it rose to 99°. Four injections of S.U.P. 36 were given at two-day intervals. In three weeks the patient was well, and was putting on flesh rapidly.

4. *Broncho-pneumonia.*—A child, aged 2½, was attended for over a week for bronchitis, going on to broncho-pneumonia. I then injected 1 c.cm. of S.U.P. 36. On the day of injection she lay cyanosed and panting, and appeared to be dying. The next day the temperature was normal, and I found her sitting up in bed, playing with her toys. Injections were continued till she was well.

5. *Bronchitis.*—A man, aged 39, developed an apyrexial cold in the head, and the catarrh spread to the larynx and then to the bronchi. He felt "seedy," but kept at work for six weeks, and then went away for change of air. On his holiday he was unable to play more than five holes of golf daily, and felt great fatigue; he coughed up large quantities of muco-pus day and night. After three days attempting to golf his temperature rose to 103°; Dover's powder and aspirin tablets, in 15-grain doses, were taken three times daily for two days without benefit. On the third day 1 c.cm. of S.U.P. 36 was injected; that night there was much less cough and sputum, and the temperature was normal next day. The night following there was no cough or sputum, and on the next day he did fourteen holes at golf without fatigue. Five days later he looked so fit that his friends could hardly believe he had had any illness at all. His treatment comprised four injections of S.U.P. 36 in all.

6. *Influenza.*—I left my evening surgery feeling symptoms of influenza; my temperature was 102.6°, and I injected 1 c.cm. of S.U.P. 36. At 9 a.m. next day it had fallen to 99°, and at 11 a.m. it was normal. I got up, and did sixteen visits in the rain and sleet. Next day I did my ordinary surgeries and forty-six visits. I felt well, but slight cough and expectoration remained. A week or so later I injected three doses of S.U.P. 36, spread over four days; all the catarrhal symptoms cleared up.

In my experience, repeated doses shorten convalescence and make recovery more thorough. I usually give 1 c.cm. for two consecutive days, and a third dose on the fourth day, unless all symptoms subside with the first injection.—I am, etc.,

Hull, Oct. 13th. W. THOMSON BROWN, M.B., Ch.B.

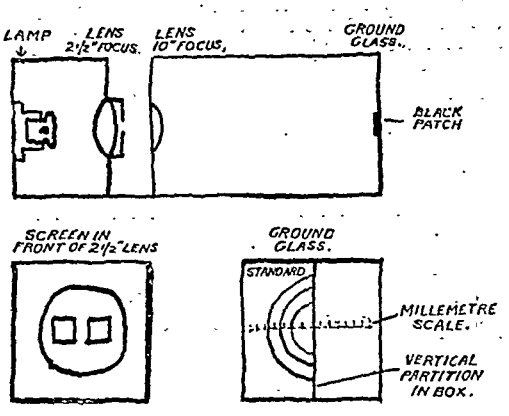
THE DIAGNOSIS OF ANAEMIAS BY DIFFRACTION.

SIR,—The recent correspondence on this subject (October 5th and 19th) induces me to describe a modification of Dr. Pijper's method which I have been using for some months.

Dr. Pijper's original method, involving a dark room and an arc light, is rather too cumbersome for the clinician. Dr. Eve's apparatus is portable, but, while giving an average measurement of the red blood cells, does not seem to permit measurement of the degree of poikilocytosis or anisocytosis.

The apparatus I have designed measures about 16 in. by 6 in. by 6 in.; it is self-contained, and cost me about 15s. (I believe Dr. Eve's halometer costs £4 4s.) Two boxes, each 6 inches square, one 4 inches long, the other 11 inches long, are mounted on a common baseboard. The smaller box contains a cheap 4½-volt flash lamp bulb of the pointolite variety, mounted opposite a double convex lens of 2½ in. focal length. The larger box has at one end a plano-convex lens of about 10 in. focal length, at the other a ground-glass screen. This box is divided vertically as in Dr. Pijper's apparatus (*British Medical Journal*, April 6th, p. 635).

The ground glass and the flash lamp are in each case at the focal distance of their respective lenses, and, once they are mounted, no further alignment is necessary. Mounted in front of the smaller box is a screen with two square holes, while the blood films are clipped to the front



of the larger box across the lens. The ground-glass screen has a scale of millimetres horizontally and a black patch centrally.

With this simple apparatus the violet, yellow, and red haloes are very clearly defined; a direct comparison is possible between a standard smear and the one under examination, and measurements of the diameters of the haloes may be quickly made. I have found it very useful, both in following the course of pernicious anaemia and in excluding that disease in numerous cases of secondary anaemia. The apparatus could easily be made more portable, if desired, by making both boxes of the collapsible bellows type. It can be used in a shaded corner of a room, a dark room being quite unnecessary.—I am, etc.,

London, S.W.16, Oct. 17th. W. EDWARDS.

THE CONTROL OF MEASLES.

SIR,—In his letter of October 19th Dr. D'Ewart draws a very gloomy picture of the consequences following in the wake of epidemics of measles. Fortunately there is another side of the picture. After an experience of twenty-five years in general practice I have become increasingly impressed with the fact that measles is neither so fatal nor so serious in its after-effects as various authorities would have us believe. This view is, of course, based on my personal experience alone.

In recent years I can remember only one death from measles, and that case was a patient of a colleague, and is therefore not included in the series of cases referred to below. On examining my records I find I have notified 153 cases of measles since January, 1924. To the cases actually notified there must be added those other cases occurring later in the same households and which are not notifiable; as it is very uncommon to have one case only of measles in a household unless the child happens to be an only child, the addition of a further 50 per cent. of cases would not be an excessive estimate, making a total of some 230 patients. All the children were attended at their own houses, the majority of them good middle-class homes. Among them there was no fatal case, and few cases with serious complications. At the present time I can trace 92 of the 153 notified cases, the remainder either having left the district or come under the care of other practitioners. In 18 cases only has the attack been

followed by other troubles, and most of these subsequent illnesses have been of such a nature that I think it would be scarcely fair to attribute them to the attack of measles which preceded them by a more or less considerable interval.—I am, etc.,

Manchester, Oct. 21st. ARNOLD GREGORY.

LIVER INTOXICATIONS.

SIR,—In your leading article (October 19th, p. 727) on some recent advances in respect of the prevention and treatment of liver intoxications, it was mentioned that the condition might well prove to have a wide clinical application. After giving details of the similarity between poisoning due to carbon tetrachloride and poisoning due to guanidine, it was pointed out that the mere administration of glucose in these cases to rehabilitate the liver cells and raise the blood sugar content was not sufficient, since it did not stabilize the carbohydrate metabolism. On the addition of calcium chloride (it was stated) the blood sugar was, however, raised, the other manifestations of nerve disturbance removed, and the general condition permanently bettered. At the end of the article it was suggested that an explanation of the pronounced effect of the administration of calcium upon the carbohydrate metabolism would be welcome.

The rise in the guanidine blood content is associated with a hypoglycaemia; just as guanidine has an action akin to insulin, synthalin (a synthetic guanidine derivative) causes hypoglycaemic convulsions with minute doses when given by the mouth. Frank and others (*Klin. Woch.*, 1926, 2100) have shown this; and Collip (*Journ. Biol. Chem.*, 1923, lviii, 163) also suggested the possibility that insulin, guanidine, and certain constituents of plant extracts were related chemically in some fundamental manner. In parathyroidectomized animals, or in animals injected with guanidine, calcium chloride prevents the onset of tetany symptoms; insulin coma convulsions can be arrested by injection of calcium chloride and parathyroid. Wherever there is a toxic action on the liver cells the metabolism is increased three- to four-fold (Whipple). The action of the calcium seems to be in neutralizing the toxic substance by combining with it and causing it to be excreted by the kidneys. In this way the liver cells are no longer irritated or poisoned; they are able to settle back at their normal metabolic level, and to retain their glycogen. Thus, the blood sugar is restored to normal if the glucose administration has been constant over the period. I have worked out this same solution for these cases, as met with in clinical work, and I write this note, therefore, to endorse what you say as to its wide applicability.

In a letter to the *Lancet* (1928, vol. ii, p. 1050) I described a series of cases with most diverse symptoms, chiefly seen between September and December of that year, where marked acetonuria was the outstanding symptom. Glucose and alkalis at first were given, and although in many of the cases the peripheral nerves showed great irritability, calcium was at first withheld, under the impression that an acidosis was always associated with an increased calcium content in blood. Later, however, it was given, and when the patients had fully corrected and their reaction had passed over to the alkaline side, they were put on to calcium chloride and parathyroid extract. Administration of any meat juices at this stage was apt to precipitate the attack, as at the very commencement of the illness. A notable feature of many of these cases was the increased excretion of urea in the urine; 2.5 per cent. was common, and several went up to 4 per cent., 4.5 per cent., and even 5 per cent. urea. This supports the increased endogenous (liver) metabolism mentioned by Whipple, and is particularly noticeable in cases with defective functioning parathyroids.

In the leading article in the *Journal* you mention the successful treatment of cases of toxaemias of pregnancy, eclampsia, etc. We used the same treatment for any such case at the time, and with success. Alkalis and glucose alone will not save such cases if severe; if my contention is correct, that the hypoglycaemia is due to the insulin (like the action of guanidine), then it would seem wrong to use glucose and insulin as suggested in some quarters.

MacLeod has stated with regard to the defective functioning of the parathyroid glands that this may not become evident at the time of stress due to pregnancy or improper diet. When this is so a diet of flesh is much more apt to bring about this condition than one containing vegetables or milk.

Space does not allow me to enter on the question of seasonal incidence (Osler says it is endemic in Norway in cold winter months), but I should like to mention a few of the types of case where this line of treatment is helpful owing to the occurrence of the same or some similar disturbance of metabolism. Under the heading "Debility in children and cyclical vomiting," you published a letter of mine on February 8th (p. 269) in which I disagreed with the suggestion that glucose or an increased carbohydrate intake was all that these patients wanted. In summing up I stated my view that in addition to the intestinal-hepatic syndrome, the question involved the *p*H of the blood, its calcium content, and the thyroid-parathyroid apparatus in its detoxicating and acid-base regulating mechanism. Since following this line I have obtained marked success with certain cases of this type. I have on several previous occasions referred to the advantage of dealing with liver metabolism in cases of hyperpiesia, angina pectoris, and cardiac arrythmias with high blood pressure, and I am glad to find that Major of Johns Hopkins and Addison of Toronto General Hospital have obtained satisfactory results along similar lines. This biochemical problem and others related to it are of very great and widespread importance in the solution of problems of disease; hence my lengthy letter.—I am, etc.,

Darlington, Oct. 19th. R. CHALMERS.

MILK A CAUSE OF ARTERIO-SCLEROSIS?

SIR,—Dr. James Holmes's interesting letter on this subject (October 19th, p. 739) contains a quotation from a paper by Dr. G. A. Allan, which seems worthy of special notice at the present time—"in almost all cases prognosis is bad, particularly in view of the absence of any evidence that arterio-sclerosis, atheroma, or calcification can be influenced materially by any known line of treatment." There are now on the market at least two types of reagents on behalf of which claims are made that they are capable of preventing calcareous degeneration, and of restoring, to some extent at least, tissues which have undergone such change. One is a preparation of silica, the other a preparation containing chlorophyll. There is in use on the Continent a preparation containing both these ingredients.

Continental investigators offer experimental and clinical evidence to support their claim that silica therapy leads to a more pliable and elastic repair of damaged tissue than calcium therapy does. The physical chemistry of silica offers some support to this contention, and suggests that silica is capable of replacing or removing lime in the tissues. Incidentally, the theory of electrolytic dissociation does not appear to hold in the case of silica in solution, and the existence of a silica "ion" (SiO_3) is said to be extremely doubtful! Colloidal silica is largely used I understand, in homœopathic medicine to reduce blood pressure; and is looked upon as almost a specific in the treatment of the sleeplessness of old age. The matter seems worthy of the attention of our experimental pharmacologists.—I am, etc.,

Buxton, Oct. 26th. P. HEFFERNAN, M.D.

MATERNAL MORTALITY.

SIR,—If Dr. Kelson Ford's assertion (October 12th, p. 692) that "some practitioners, even to-day, do not scrub their hands before applying forceps, do not have their instruments boiled before use," and "decline sterile towels when offered them" has any foundation in fact I fear the standard of work done in his area must be very low, or, alternatively, Dr. Ford is laying himself open to a charge of libelling his fellow practitioners.

The art of midwifery can be acquired only by long experience, built upon a foundation of sound knowledge of anatomy, physiology, medicine, and surgery; can one credit

the midwife, however well trained she may be, with such knowledge? Labour is a process in which at least two lives are dependent upon the skill and care of the accoucheur; yet in this vital matter a large proportion of the community are forced, on economic grounds, to rely upon the services of the midwife. It is our duty, therefore, to devise a scheme whereby expert help may be given to every lying-in woman in the land. Labour, after all, is not an emergency; it can be legislated for in advance. For at least thirty weeks contributions could be made by those wishing to avail themselves of such a scheme. This could be done through the Post Office, and when thirty payments of, say, one shilling, have been made, the amount could be doubled by a grant from the Exchequer and a form, made out as a crossed cheque, passed to the woman for presentation to her doctor.

This would not be a costly scheme. In fact, if everybody took advantage of it, it would cost the country roughly about £1,750,000 per annum; but, as many would not need this assistance, the cost would work out at less than one million. Compared with other schemes under consideration at the present time, this is a very modest one, more especially when one considers the enormous benefits which it would confer on the mothers of the country, and a real step would be taken in the direction of reduction of both maternal and infantile mortality. Moreover, our hospitals would benefit by the substantial reduction in maternal morbidity which is bound to ensue. Of course, this scheme would not interfere with the working of the National Health Insurance Act, but would be an adjunct thereto. It would be of great assistance to the wives of uninsured men with small incomes.—I am, etc.,

Manchester, Oct. 14th. D. C. MACDONALD.

QUININE AND BLACKWATER FEVER.

SIR,—Though without any professional qualification, you may perhaps allow me to make some remarks on the real or supposed relations between quinine medication and blackwater fever, a subject treated in your current number (October 19th, p. 729). There seems little doubt that there is some connexion, but what is it? So far I have not seen noted the belief of many medical men of great experience in malarial countries that this fever is due not to overdosing with quinine, or to its entire lack, but rather to its use over a long period in insufficient and ineffective quantities. It is not always easy to obtain medical help at once, and the common erroneous belief that a few grains of quinine taken daily act as a prophylactic leads those suffering from slight "chills and fever" to take the drug in doses which have no other effect than the postponement of the real attack. If such patients took 30 or 40 grain doses at once, instead of 5 grains a day, it is possible that blackwater would rarely occur.

As those on whose authority I rely in saying so much are too far away from me to get permission to use their names, perhaps the mere unsupported suggestion may lead some of your readers to say whether their tropical experience seems to lend support to this view.—I am, etc.,

London, Oct. 19th. MORLEY ROBERTS.

THE ROYAL COMMISSION ON THE ALCOHOL QUESTION.

SIR,—Surely the function of this Royal Commission is mainly judicial? Is it not a pity that any interests—the trade, avowed temperance reformers, or the profession of medicine—should be represented on the Commission? Would it not be much better for all such interests to lay their views before the Commission as witnesses rather than to sit on the Commission with their views already formed and publicly known—a state of affairs which can only lead to at least one minority report being produced, and possibly to no report being supported by enough commissioners to give it the weight which should be attached to the report of a Royal Commission?—I am, etc.,

Monmouth, Oct. 21st. N. S. B. VINTER.

Obituary.

DR. HOWARD MARSHALL, O.B.E., who died on October 9th, at the age of 58, received his medical education at Cambridge and St. Bartholomew's Hospital. He graduated M.B., B.Ch. in 1895. After holding house appointments at St. Bartholomew's and the Nottingham General Hospital, he practised for five years at Bexhill, where he was also medical officer to the Metropolitan Convalescent Home. In 1902 he went to Cirencester, as partner to the late Mr. O. H. Fowler. While conducting an extensive practice, Dr. Marshall won considerable reputation by reason of his surgical ability, and was appointed surgeon to the Cirencester Memorial Hospital; at the time of his death he was the senior member of the honorary medical staff. He associated himself actively with the extensions and improvements of the hospital from time to time, and was largely responsible for the establishment of an employers' and workers' voluntary contribution scheme in connexion with it. He was also medical officer to the Royal Agricultural College, Cirencester, and civil surgeon to the 4th Battalion of the Gloucester Regiment. On the outbreak of war a Red Cross Hospital came into being at Bingham Hall, and Dr. Marshall was appointed medical officer in charge of it; in 1920 he received the O.B.E. in recognition of the particularly valuable services he rendered in this way. Dr. Marshall was a member of the British Medical Association, and president of the Gloucester Branch from 1915 to 1917. He took special interest in the effort to regularize the position of civil surgeons called upon to provide attendance for military patients during the war. Throughout his life he was devoted to outdoor sports; in his student days he was distinguished as a Rugby footballer, gaining an international cap as half-back.

WE regret to announce the death of Dr. JAMES MORRISON GARDINER BREMNER, O.B.E., on October 12th, at his residence in Norwich. James Bremner was born in Banffshire, and received his medical education in Aberdeen, where he graduated M.B., C.M. in 1894. Soon afterwards he went to Norwich, and for a period of more than thirty years he resided there, building up a large practice and acquiring varied and numerous associations. He early became attached to the Territorials, joining the Norfolk Regiment. In 1914 he received a commission as major, and took command of the Second East Anglian Field Ambulance; in the following autumn he was gazetted lieutenant-colonel. His personal knowledge of training, organization, and equipment enabled him as an officer in command to place in the field a unit which did very fine work. In July, 1915, he took part in the landing at Gallipoli, where he remained until the evacuation. After accompanying his unit to Mudros, and thence to Egypt, he was stationed at the Suez Canal after the push forward to Gaza. After three battles there he accompanied his ambulance as far as Ludd. In the spring of 1918 he took charge of a large convalescent home at Alexandria. Immediately after the war he resumed his medical work in Norwich, and his deep interest in Freemasonry and the local Scots Society found outlet in renewed activity. In Freemasonry he occupied a high position; in 1908 he became Provincial Grand Director of Ceremonies, and in 1920 was raised to the high rank of Provincial Grand Standard Bearer. The local Scots Society will also find it difficult to replace him, for much of the success it enjoys to-day was due to his enthusiasm. A colleague writes: In his profession Dr. Bremner was an assiduous and painstaking clinician; his quiet and sympathetic directness always arrested the attention and won the confidence of his patients. He was a man whose desire it was that no ostentation or public acknowledgement should attend any act of his. Quietly and gently disposed, it may be said that sincerity was the keynote of his whole life. Among a host of friends his memory will be widely treasured for many fine qualities of personal service, far outlasting more brilliant or more blazoned achievements.

The Services.

HONORARY PHYSICIANS TO THE KING.

LIEUT.-COLONEL R. B. AINSWORTH, D.S.O., O.B.E., R.A.M.C., and Lieut.-Colonel E. C. Hodgson, D.S.O., I.M.S., have been appointed Honorary Physicians to the King and promoted to the brevet rank of colonel.

DEATHS IN THE SERVICES.

Lieut.-Colonel Daniel Nicholas Martin, Bengal Medical Service (ret.), died at Rowlands Castle, Hants, on October 3th, aged 84. He was born on August 4th, 1841, the second son of the late Robert Martin, Esq., of Castle Fane, Glanmire, county Cork, was educated at Queen's College, Cork, and graduated as B.A., M.D., and M.Ch. of the Queen's University, Ireland, in 1869. Entering the I.M.S. as assistant surgeon on October 1st, 1869, he attained the rank of brigade surgeon lieutenant-colonel on February 28th, 1898, and retired with an extra pension on May 1st, 1899. He served in the Afghan war of 1879-80, receiving the medal, and in the Mahsud Waziri campaign of 1881, for which no medal was given. Most of his service was in military employ, when he was for many years medical officer of the old 30th Punjab Infantry; but the last few years of his service were spent as a civil surgeon in the Central Provinces.

Major Robert Napier Buist, R.A.M.C. (ret.), died at Tunbridge Wells on October 2nd, aged 67. He was born in India on December 28th 1861, the second son of the late Major-General D. S. Buist, Indian Army, was educated at Edinburgh University, where he graduated as M.B. and C.M. in 1885, and entered the army as surgeon on July 28th, 1886. He attained the rank of major after twelve years' service, and retired on July 28th, 1906.

Corrigendum.—We regret that in this column, in our issue of October 12th (p. 700), the name of the late Lieut.-Colonel J. J. C. Donnet was misspelt.

Universities and Colleges.

UNIVERSITY OF OXFORD.

AT a congregation held on October 17th the degree of Bachelor of Medicine (B.M.) was conferred on B. R. Caygill.

UNIVERSITY OF CAMBRIDGE.

AT a congregation held on October 18th the following medical degrees were conferred:

M.D.—W. W. McLean, N. F. C. Burgess, F. B. Parsons.
M.B., B.CHIR.—*A. D. Charters, J. C. Gordon, H. Bell.
M.B.—L. Shiito.
B.CHIR.—N. L. White.

* Admitted by *proxy*.

UNIVERSITY OF ST. ANDREWS.

ON the occasion of the installation of Sir Wilfred Grenfell, K.C.M.G., M.D., as Rector of the University on November 6th, the Senatus Academicus will confer upon him the honorary degree of LL.D.

UNIVERSITY OF DUBLIN.

SCHOOL OF PHYSIC, TRINITY COLLEGE.

THE following candidates have been approved at the examination indicated:

FINAL MEDICAL (*Part I, Materia Medica and [illegible], Jurisprudence and Hygiene; Pathology*).
Ennis: *G. A. Wray, *R. O'Brien, *A. A. M. G. Leane, O. W. S. Fitzgerald, H. Y. T. A. D. Barber, T. J. O Sullivan, Annie [illegible], D. Egan, J. A. Page, C. M. Elliott, T. H. Dockrell, R. D'Scott, W. M. E. Anderson, J. Elliman.

* Passed on high marks.

NATIONAL UNIVERSITY OF IRELAND.

UNIVERSITY COLLEGE, DUBLIN.

THE following candidates have been approved at the examination indicated:

D.P.H.—*Part I*: C. J. Ellison, P. P. McNamara. *Part II*: *Catherine M. O'Brien, †M. Hanly, †H. Macken, †E. R. Waldron, †E. A. Grant, †P. Fleming, †T. Feeney, †M. A. Cooney, J. J. L. Cox, T. J. Kirby, Mary K. McGloughlin, A. B. O'Malley, E. White.

* First-class honours. † Second-class honours.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE annual Buckston Browne dinner of Fellows and Members will be held at the College on the evening of Thursday, November 14th.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

AT a meeting of the Royal College of Surgeons of Edinburgh held on October 16th, when Mr. Alexander Miles, M.D., LL.D., President, was in the chair, the following 33 successful candidates, out of 108 entered, having passed the requisite examinations in July, were admitted Fellows:

J. W. Anderson, R. S. Aspinall, G. H. Burnell, J. H. Coolican, R. Cormack, N. R. Cotton, D. E. Cuffey, R. T. Desai, T. S. Donovan, E. A. Fiddian, A. A. Fothergill, J. R. Godsall, S. J. P. Gray, V. C. J. Harris, L. Herzenberg, G. L. Khirwadar, Beryl P. Lye, J. T. McOuat, D. G. Martin, D. M. W. Maxwell, G. W. Milton, B. G. Mitford, J. E. Monro, G. J. Murray, E. W. M. H. Phillips, G. F. Rich, W. B. Smellie, A. C. Thomas, M. E. Tiruchelvam, C. H. Watson, F. L. Webster, L. B. Wevill, N. A. J. Young.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

THE annual meeting was held on St. Luke's Day, October 18th. Dr. Alice Barry was unanimously elected a Fellow of the College.

Dr. William Arthur Winter was elected President and Dr. J. A. Matson was re-elected Vice-President.

The following were elected censors of the College: Medicine, Dr. Matson and Dr. Micks; medical jurisprudence and hygiene, Dr. Wigham; midwifery, Dr. Spencer Sheill.

The following officers were re-elected: Representative on the General Medical Council, Sir John Moore; treasurer, Dr. H. Bewley; registrar, Dr. T. P. C. Kirkpatrick; librarian, Mr. R. Phelps.

The representatives on the committee of management under the conjoint examination scheme were re-elected as follows: Dr. Walter Smith, Sir John Moore, and Dr. T. P. C. Kirkpatrick.

CONJOINT BOARD IN SCOTLAND.

THE following candidates have been approved at the examination indicated:

FINAL EXAMINATION.—*Medicine*: R. F. L. V. Harvey, Florence L. M. Millard, E. O. Hagedorn. *Surgery*: G. R. Parker, P. van der Lith. *Midwifery*: G. R. Parker, G. Henderson, P. van der Lith, T. H. Oh, Florence L. M. Millard, E. O. Hagedorn. *Medical Jurisprudence and Public Health*: M. K. Yong, C. C. Teck, A. I. Sayhid, Mary McF. Buchanan, A. Brock, W. E. MacDonnell, S. Y. Bajah, W. R. Young, T. W. Millar, H. C. Bodemer, Ethle E. Keighley, G. Brown, J. W. McGregor, M. N. Rozdon.

Out of 75 candidates entered, the following passed the Final Examination, and have been admitted L.R.C.P.Ed., L.R.C.S.Ed., L.R.F.P. and S.Glasg.:

H. P. Lawson, E. C. Thomas, H. C. Franz, C. J. Poh, J. Kearney, W. Smith, A. Medwar, F. K. Fenton, Annott, D. Gould, W. O. Molander, J. Sam-, W. P. Kennedy, T. S. M. San- Jolhe, banthiam, J. Elliott, S. Th. S. A. Kelaney, K. C. K. E. Raja, A. E. Daviot.

Medical News.

THE Norman Lockyer Lecture before the British Science Guild will be given by Sir Walter Fletcher, K.B.E., M.D., F.R.S., at the Goldsmiths' Hall, Foster Lane, E.C.2, on Tuesday, November 19th, at 4.30 p.m., when he will speak on certain aspects of medical research and their applications.

THE Schorstein memorial lecture at the London Hospital Medical College will be delivered in the Bearsted Clinical Theatre by Dr. A. F. Hurst on Friday, November 8th, at 4.30 p.m.; the subject will be "Precursors of carcinoma of the stomach." Members of the medical profession are cordially invited.

As will be seen from our advertisement columns, applications for a Fouleron research studentship of the Royal Society, at an annual stipend of £700, must be received by December 9th. The studentship is for three years, but may be renewed from year to year to a total of six years in all. The duties of the student will be to conduct researches in medicine or the contributory sciences under the supervision of the management committee, to whom he or she will be required to report from time to time. Particulars may be obtained from the assistant secretary of the Royal Society, Burlington House, Piccadilly, W.1.

THE annual dinner of the Society of Medical Officers of Health will be held at the Piccadilly Hotel, London, W., on Thursday, November 14th, at 7.15 for 7.30 o'clock.

THE annual dinner of the West Riding Association of the graduates of the University of Edinburgh will be held at the Midland Hotel, Bradford, on Wednesday, November 13th, at 7.15 p.m. The guest of the evening is Dr. Logan Turner. The general meeting of the society will be held prior to the dinner at 6.30 p.m. Further information may be had from the Honorary Secretary, 33, Manor Row, Bradford.

PRINCESS MARIE LOUISE will lay the foundation stone of the first block of the new Queen Charlotte's Maternity Hospital in Hammersmith on November 4th, at 3 p.m. Guests are requested to arrive not later than 2.30 p.m., at 339, Goldhawk Road, W. A description of the new building appeared in our columns on September 7th (p. 473).

UNDER the auspices of the British Institute of Philosophical Studies Mr. E. S. Russell will give a course of six lectures at University College, London, Gower Street, W.C.1, on the interpretation of development and heredity. The lectures will be given on Mondays at 5.[illegible] ember 4th. Full information may be [illegible] to the Director of Studies, 88, Kingsway, W.C.2.

THE University of Sheffield commenced a new series of nine post-graduate clinics on October 18th, when Dr. Imrie gave a demonstration of [illegible] and the methods employed in their [illegible]. The [illegible] clinic takes place to-day (Friday, [illegible], when Dr. Skinner will discuss gastro-intestinal disorders of neurological origin. In response to a suggestion that a series of clinics might usefully be devoted to some special subject, it was arranged to devote the first six clinics of the course to gastro-intestinal disorders. No fee is charged for attendance at the clinics, which are held at the Royal Hospital, Sheffield, on Fridays, at 3.30 p.m. The last of the series will be held on December 13th. Afternoon tea will be served.

A COURSE of six lectures on smoke abatement will be given at the College of Technology, Manchester, on Fridays, from November 8th to December 13th, at 7 p.m. The lectures will deal with the nature of combustion, the direct and indirect effects of smoke on health, the employment of smokeless fuels, and the abatement of domestic and industrial smoke. Further information may be obtained from the secretary of the National Smoke Abatement Society, 23, King Street, Manchester.

A SHORT course of lectures on functional nervous disorders for practitioners and students will be given at the Tavistock Square Clinic for Functional Nervous Disorders, 51, Tavistock Square, W.C.1, commencing on Monday, November 11th, and concluding on Saturday, November 23rd. The fee for the course to medical practitioners is £2 2s. and to medical students 10s. 6d. Tickets for the course may be obtained in advance from the honorary secretary at the clinic.

THE Fellowship of Medicine announces that lectures will be given in the lecture room of the Medical Society, 11, Chandos Street, Cavendish Square, on the following dates: Monday, October 28th, at 5 p.m., by Dr. Maurice Davidson, on "*Coughs*" (*free to medical practitioners*); Tuesday evening, October 29th at 8.30, by Dr. A. F. Hurst, on "Recent work on disorders of the stomach"; and on Friday evening, November 1st, at the same time, by Dr. J. W. McNee, on "Recent views on diseases of the liver and biliary tract." The last two lectures are part of a series especially suitable for M.R.C.P. candidates. A demonstration of cases in the wards will be given by Sir Thomas Horder at St. Bartholomew's Hospital on October 31st, at 1.30 p.m.; a demonstration of gynaecological cases will also be given by Mr. McKim McCullagh at the Samaritan Hospital, Marylebone Road, on October 30th, from 10 a.m. to 12.30. Both demonstrations are free to medical practitioners. The second week of the special post-graduate course in medicine, surgery, and the special departments will continue at the Metropolitan Hospital, Kingsland Road, from October 28th to November 2nd, the daily sessions lasting from 10.30 a.m. to 5.30 p.m. On Friday, November 1st, Professor Dame Louise McIlroy will give the first of four weekly demonstrations in ante-natal treatment at the Royal Free Hospital at 5 p.m. The subjects of courses in November include: medicine, surgery, and gynaecology; venereal disease; proctology; and orthopaedics. Copies of all syllabuses and tickets of admission may be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

A CLINICAL meeting will be held at the East London Hospital for Children and Dispensary for Women, Shadwell, on Wednesday, November 6th, at 4.15 p.m., when cases of interest will be demonstrated in the wards. Tea at 4 p.m. All practitioners will be welcome.

A FESTIVAL service in connexion with St. Luke's Day was held in St. Albans Cathedral on Sunday, October 20th, for medical practitioners of Hertfordshire and Bedfordshire, nurses, voluntary aid detachments, and members of the St. John Ambulance Brigade of the diocese. The lessons were read by medical practitioners, and the Dean of St. Albans delivered an eloquent address, entitled "Fellow workers with God." Before the service Dr. J. H. Gilbertson of Hitchin inspected the St. John Ambulance Brigade representatives, who numbered more than 150; after the service the congregation had tea together.

THE annual autumn meeting of the medical missions department of the Society for the Propagation of the Gospel in Foreign Parts was held on October 21st, at the Caxton Hall, Westminster, after a conversazione which had been attended by medical practitioners and nurses from overseas. The speakers included Sir Leonard Rogers, the Bishop of Assam, Dr. H. H. Weir, Dr. Mary Geil (China), and Miss H. Monkhouse (India).

THE annual festival service of the Guild of St. Luke was held in Westminster Abbey on Sunday evening, October 20th. The Bishop of Bradford in his sermon emphasized the need of such an increase in faith as was characteristic of the early Church. Members of the Guild of St. Luke were pledged to be men and women of prayer, and to give encouragement and support to others in leading a Christian life. They represented and assisted the work of medical missionaries abroad, and they must associate themselves actively with the promotion of an optimistic view of a campaign which should triumph over evil generally. During the service there was a procession of medical practitioners in academic robes, which included Mr. St. Aubyn Farrer, Provost of the Guild, Dr. Culver James, Vice-Provost, Dr. Andrew Currie, honorary secretary, and the Rev. Dr. Kirkland Whittaker.

THE second report of the Legislation Subcommittee of the Ministry of Health Advisory Committee on Water has now been published by H.M. Stationery Office, price 9d. It reviews the position as regards the existing legislation with respect to water supply, and proposals are submitted with a view to bringing the legal provisions up to date.

THE annual congress of German medical historians was held at Budapest on September 6th, when twenty-six papers were communicated, and the president, Professor Karl Sudhoff, delivered a speech in honour of Ignaz Semmelweis (1818-65), and laid a wreath at the foot of his statue.

THE *Yorkshire Post* of October 10th contains an interesting reference to the problem of the financial burden thrust upon hospitals in respect of the treatment of the victims of motor accidents. In an editorial reference the opinion is given that whatever is done in providing compensation should be on a national and not on a local basis. In a letter appearing in the same issue of the *Yorkshire Post* Colonel W. L. Kirby, chairman of the County Hospital, York, suggests that the addition of 1s. a year to the existing cost of a driver's licence would provide a sum which might be the nucleus of a central fund for distribution to all voluntary hospitals. Colonel Kirby also supports the plea that a small part of the Road Fund might be allocated to this useful purpose.

THE National Association for the Prevention of Tuberculosis has, during September and October, conducted educational tours in Angus, Perthshire, Berkshire, Staffordshire, Nottinghamshire, Essex, Leicester, Bolton, Glossop, Ipswich, Gateshead, Oldham, and Barnes.

ON October 11th, at Plymouth, Mr. T. Young Simpson, O.B.E., M.D., M.S., F.R.C.S.Ed., was presented with a walnut compactum and an illuminated autograph book from many of his medical colleagues on his retirement from practice on account of ill health due to overwork.

THE Medical Society of Budapest has recently celebrated the centenary of the birth of Friedrich von *Korányi* (1828-1913), who was noted for the introduction of cryoscopy of the blood and urine, the benzol treatment of leukaemia, several valuable works on tuberculosis, and his interest in post-graduate teaching.

DR. THEODOR AXENFELD, professor of ophthalmology at Freiburg i. Br., has been awarded the Lucien-Howe gold medal by the American Ophthalmological Association, and Dr. Ernest Fuchs, professor of ophthalmology at Vienna, has been awarded the Leslie-Dana gold medal.

THE two German journals devoted to anaesthetics, *Schmerz* and *Narkose und Anaesthesie*, in the issue of July 15th united to form a single organ entitled *Schmerz, Narkose-Anaesthesie*, under the editorship of C. J. Gauss of Würzburg, B. Behrens of Heidelberg, and H. Franken of Freiburg.

WE have received a copy of the first issue of the *Collected Papers* of the Lockwood Clinic at Toronto. This brings together under one cover reprints of articles published during recent years in various medical journals by Dr. Ambrose L. Lockwood and some of his colleagues.

A COUNCIL has recently been formed in Sydney to investigate the social and physiological effects of alcohol. The president is Mr. I. V. Newman of the botanical research department of Sydney University, and Dr. Arthur, Minister of Health for New South Wales, vice-president.

A PROPOSAL to abolish regulated prostitution has recently been rejected by a small majority in the Japanese Parliament. The Director of Public Health pointed out that venereal disease occurred in only 13 per cent. of the registered women, as compared with 32 per cent. of the unregistered.

A SOCIETY has been founded in New York, with a capital of a million dollars, to undertake further investigations on poliomyelitis.

DURING 1928 there were 25,764 deaths in Vienna, or 13.3 deaths per thousand inhabitants, and 19,744 births, or 10.2 births per thousand inhabitants.

DR. MAX RUBNER, professor of hygiene and physiology of Berlin University, has been elected an honorary member of the Physiological Society.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to *The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.*

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The *TELEPHONE NUMBERS* of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The *TELEGRAPHIC ADDRESSES* are:

EDITOR of the *British Medical Journal, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocria Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 21361 Edinburgh).

QUERIES AND ANSWERS.

TREATMENT OF THYROID CYSTS.

"F. S." asks if there is any known method of treating thyroid cysts by injections.

SUN BATHING.

"N." wishes for details of the construction and main requirements of sun baths in this country, and asks where information may be acquired, either in books or by visits to certain places.

FLEAS.

"T. G. P." (Aylesbury) writes in reply to "W. G. H." (p. 744), who asked how to keep fleas away: *This method has proved satisfactory.* Enclose in each of four small bags a piece of camphor, 1 in. square and 1/2 in. thick; with a small safety pin attach them to the inside of the trousers, about the ankle level. Most fleas gain entrance at this spot.

INCOME TAX.

Cash Receipts Basis.

"H. E. H." has been in practice for many years, and has been assessed on the basis of cash receipts. In July last he bought an additional practice, which has been amalgamated with his previous one. The inspector of taxes proposes to tax the earnings of the additional practice separately, on the basis of the book debts, and not on that of the cash receipts. The two practices have become so intermingled that separation of the receipts is impracticable.

*** On the facts explained it would be legally incorrect, in our opinion, as well as most inconvenient, to make separate assessments in respect of the two practices—which have, in effect, become one. On the other hand, "H. E. H." cannot claim to apply the cash receipt basis to the new practice as now constituted, because the cash receipts from that portion of it which results from the purchase of the additional practice will not, in the first year or so, represent a fair computation of the "income" therefrom, as calculated according to the Income Tax Acts. The best solution to a somewhat troublesome problem seems to us to be as follows:—July, 1929, to April 5th, 1930: "H. E. H." to accept liability on the amount of the existing assessment, or on the amount of the bookings from that practice for that period, *less any additional current* expenses incurred through taking over the additional work. Year to April 5th, 1931: Take the cash receipts of the year to December 31st, 1929, *plus* the probable amount received by the vendor of the new practice in the period January to June, 1929, *less* the expenses incurred by "H. E. H." in the year to December 31st, 1929, and those incurred by the vendor in the period January to June, 1929. The above may be open to some objection on strict technical grounds, but would provide an equitable settlement.

Payment of Indian Income Tax.

"N. D. D." explains that he receives dividends—on shares in the name of his wife and his children—on which Indian income tax has been paid of, say, about 22d. in the £, and he pays here an additional income tax to bring up the total payment to the full rate of 4s. in the £. He encloses a circular received from the company, and inquires whether he is not paying too much.

*** He is chargeable at 4s., *less* the relief provided. That relief cannot exceed half his "appropriate rate," and as that rate appears to be 4s., the maximum relief would be 2d. in the £, whereas he has received relief at 22d. in the £. Whether he should receive a further 2d. in the £ will depend on the amount of the refund which he can claim from the Indian Revenue under Section 43 of the Indian Income Tax Acts of 1922 and 1923, on which he can obtain advice on application to the High Commissioner for India in London. What is probably a more important point is that if his children are beneficially entitled to the income arising on the shares which stand in their names, then they are not taxable in this country as part of "N. D. D.'s" income, though the reverse is the case with the income on his wife's shares. This is a point which he would be well advised to take up with his local inspector of taxes at an early date.

Separate Assessment of Husband and Wife.

"CERNOS" (whose inquiry was answered on September 21st, p. 565) writes again with regard to the calculation of the allowances due to his wife and himself separately, sending additional particulars.

*** The allowances appear to be correctly calculated; the marked difference between the years 1927–28 and 1928–29 is due to the change in our correspondent's own income, following on the sale of investments and the purchase of an annuity.

LETTERS, NOTES, ETC.

PRESCRIBING BY CIRCULAR.

"C." writes: A few days ago I came into possession of a circular, copies of which had apparently been sent to all the customers on *the books of a certain chemist. This circular advertised cachets* of thyroid and manganese for trial to members of the general public in cases of "asthma, rheumatism, blood pressure, obesity (stoutness), intestinal troubles, acne (pimples and blotches), kidney troubles, neuritis, and all other troubles which are caused by auto-intoxication." It scarcely seems right that a chemist should *circularize the public in such a manner*, since thyroid and manganese is not a preparation which can be taken with impunity without medical supervision. Surely the doctor is the one to say whether this treatment is suitable for any particular case, and not the chemist. Is it not against the ethical code of pharmacists to purloin a mode of treatment from the medical *journals and advertise it wholesale to their customers?* How can it be prevented?

AN IRISH MEDICAL POET.

"IRISH GRADUATE" writes: I desire to draw attention through your columns to the proposed publication of the letters of Dr. Drennan, the Belfast patriot, poet, and doctor, who lived at the end of the eighteenth and the beginning of the nineteenth centuries. Dr. Drennan was the author of the well-known poem "When Erin First Rose" and other poems; he was in close contact with many well-known figures in a stirring period of Irish history. Those who desire to support the publication should send their names to the Deputy Keeper of Public Records, Public Record Office for Northern Ireland, Murray Street, Belfast, or H.M. Stationery Office, Custom House, Belfast. The price of the publication will be 7s. 3d., post free, but the volume will only be brought out if sufficient subscribers are obtained. Those who wish to make the publication possible should write at once to one of the above addresses.

HERPES AND VARICELLA.

DR. E. J. BOSCHI (Bruton, Somerset) writes: On August 26th I was called to see a woman, whom I found to be suffering from rather severe frontal (supraorbital) herpes. Exactly fourteen days later, September 19th, three of her children developed varicella. At the time, so far as I can ascertain, there were no other cases of varicella in this district.

ERRATUM.

IN the final correction of Dr. F. G. Chandler's paper on "Conditions Simulating Pulmonary Tuberculosis" (published last week), a regrettable error was perpetrated by the substitution of one line for another. Line 11 in the first column of page 707 is obviously out of place and distorts the sense of the whole sentence. This, which begins in line 9, should read as follows: "In 1924 I made, with my house-physician Dr. S. Isbo, an investigation into the question of whether the faecal examination for tubercle bacilli was of real practical clinical value."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 48, 49, 50, 51, 54, 55, 56, 57, and 58 of our advertisement columns, and advertisements as to partnerships, assistantships, [illegible] 53.

A short summ [illegible] advertisement columns appear [illegible]

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

359. Syphilis of the Stomach.

J. A. JOHNSON (*Minnesota Med.*, August, 1929, p. 496) reports the case of a man, aged 54, who contracted syphilis when 35 years of age. He was treated energetically for several years, but on admission to hospital in 1922 his Wassermann reaction was strongly positive. Since 1918 he had complained of indigestion, flatulence, and pyrosis; a year later severe pain and vomiting occurred after a heavy meal. The vomiting grew worse and he lost 33 lb. in weight. A skiagram showed almost complete obstruction in the lower third of the stomach, and a large tumour could be felt; there was slight melaena and no free HCl in the gastric contents, with moderate anaemia. An exploratory operation revealed great thickening of the stomach wall, with grey striations, especially over the fundus, resembling linitis plastica, or "leather-bottle stomach." There was generalized hypertrophy, especially at the pylorus, and extensive adhesions between the duodenum and liver. A posterior gastro-enterostomy was performed and a condition typical of gastric syphilis was present—extensive mucosal atrophy with hypertrophy of the submucous and muscular coats. Three years later the patient reported that he had had no trouble since the operation. He received antisyphilitic treatment for two years and regained health. J. M. HAYES (ibid., p. 496) believes that gastric syphilis is not as rare as was formerly believed: it is estimated to occur once in about 300 gastric lesions. Various authors have reported 115 cases. The condition may occur in either congenital or acquired syphilis, and gastric symptoms appear from four to twenty-five years after the initial lesion. The average duration of symptoms is about eight years; these simulate gastric or duodenal ulcer, or cholecystitis. Pain is usually severe immediately after meals and at night. Anacidity or achylia is present, probably due to mucosal destruction. The pain is frequently relieved by alkalis, but not by food. Considerable emaciation without cachexia may occur. Gastric deformity, usually of the hour-glass or dumb-bell type, due to sclerosis of the middle portion of the stomach, occurs, and the symptoms then become severe. A palpable tumour or six-hour residue is rare. Under specific treatment symptoms usually disappear, but the deformity remains. Hayes describes the case of a married woman, aged 31, who could give no history of a primary lesion, although her Wassermann reaction was strongly positive. In 1920 she had attacks of severe nocturnal epigastric pain, relieved by medicines for three years, when perforation of a gastric ulcer occurred. The pain was relieved, but the dyspepsia persisted after an operation. In 1924 she married and had a healthy child, but in 1926 epigastric pain after meals recurred, and skiagrams showed a typical dumb-bell deformity. Antisyphilitic treatment was given and the symptoms disappeared. In 1928 she had a sudden severe haematemesis and the haemorrhage recurred in spite of repeated transfusions. At an operation extensive adhesions between the anterior gastric wall and the abdominal wall were found, with a large ragged ulcer in the posterior wall perforating into the pancreas; around the ulcer the gastric wall resembled the "leather-bottle" stomach. The ulcer was excised with a large portion of the lower gastric wall; a high gastro-enterostomy was performed and the wound closed without drainage. The patient made a good recovery and has had but little trouble since. Skiagrams show that the stomach is now almost normal.

360. Isolated Hepatic Tuberculosis in Epidemic Encephalitis.

P. NAYRAC and J. DUBOIS (*L'Écho Méd. du Nord*, September 7th, 1929, p. 423) describe the case of a woman, aged 22, who died early in 1929, after a sudden exacerbation of hypertonic symptoms, with fever and wasting; she had suffered from Parkinsonism and the typical physical and mental changes following an acute attack of epidemic encephalitis in 1919. At the necropsy the usual degenerative and inflammatory changes at the base of the brain and nerve cells were found. No other changes of importance were discovered elsewhere in the body, except in the liver. This organ was normal in size, but on microscopical examination degenerative changes were detected in the lobules, and there were one or two collections of round cells with epithelioid cells at the centre of the masses. A careful search through many preparations revealed only two giant cell systems, but these were so typical of tuberculous lesions that, in spite of their infrequency in the preparations, the authors consider that the liver was undoubtedly affected with tuberculosis. Discussing the etiology, the authors prefer to regard this case as an example of "isolated" tuberculosis of the liver, primary affection of the viscus being virtually unknown. In their opinion the known tendency of the encephalitic virus to damage the liver secondarily to the central nervous system was in this case responsible for the breaking down of the ordinarily high resistance of the liver to a tuberculous infection arising in some unknown focus.

361. Inverted Landry's Paralysis.

E. N. BOUDREAU (*New York State Journ. of Med.*, August 12th, 1929, p. 1001) records the case of a man, aged 41, who during an epidemic of poliomyelitis, after a few days' malaise and abdominal discomfort, noticed weakness and numbness of the lip muscles on the left side. About ten days later he began to have difficulty in moving the food round in his mouth. Weakness of the left side of the face then became apparent and salivation developed. The symptoms disappeared for a month; he then began to have difficulty in swallowing, and a little later developed fibrillary twitching of the right deltoid and other muscles of the upper arm. The symptoms progressed slowly, and death ensued about six months after the onset. The nucleus of the twelfth nerve was thus first affected, but the process later involved the ninth and tenth nuclei and then the cervical segments of the right side. Possibly the left seventh or fifth nerve (descending or spinal portion) was first involved. There was no necropsy.

Surgery.

362. Aplasia of the Gall-bladder.

A. W. MEYER (*Deut. Zeit. f. Chir.*, September, 1929, p. 410), who records an illustrative case, states that aplasia of the gall-bladder is frequent in many animals, but is very rare in man, only one previous surgical case having been described by Kehr. Meyer's patient was a man, aged 21, whose parents had had repeated attacks of biliary colic, his father having been operated on twenty years previously on this account. The patient himself had suffered from abdominal pain, usually at night, for five years. Owing to an unusually violent attack laparotomy was performed. No trace of a gall-bladder could be found, but a fibrous cord extending from the usual site of the gall-bladder to the duodenum was exposed and resected. There were two hepatic ducts, which united shortly before entering the duodenum. No ulcer was found in the stomach or duodenum, and the pancreas, spleen, and appendix were quite normal. Apart from bilateral parotitis, which was perhaps due to haematogenous infection from the bile ducts, recovery was uneventful, and the patient was in good health three years later.

363. Ocular Symptoms of Fractures of the Base of the Cranium.

IN some cases of cranial injuries doubt may arise as to whether the lesion is really a fracture of the base or merely a cerebral contusion. In such cases certain ocular symptoms may be noted which entirely eliminate the diagnosis of contusion, and, even when occurring alone, not only establish that of fracture, but also locate its site. H. VILLARD (*Paris Méd.*, September 7th, 1929, p. 191) describes these symptoms, and divides them into two main groups: those of vascular, and those of nervous origin. The vascular symptoms are palpebro-conjunctival ecchymosis and pulsatile exophthalmia. The former, which is often associated with a slight exophthalmia due to an orbital haematoma, is of no significance unless it occurs immediately after the injury. Pulsatile exophthalmia, symptomatic of an arterio-venous aneurysm due to a communication between the internal carotid and the cavernous sinus, is a much less frequent and much later symptom. Neurological symptoms can appear in the four nervous systems of the eye—the sensory, sensorial, motor, and sympathetic. Usually only one of these is affected, but in certain lesions two—as a rule the sensorial and motor—may be implicated. Lesions of the sensory nerve (the trigeminal) are extremely rare in fractures of the base. They cause either an anaesthesia or neuralgia in the region supplied by this nerve, and occasionally a neuro-paralytic keratitis is seen. Much less rare are disorders of the sensorial system due to injuries of the optic nerve, which cause a partial or total paralysis of this nerve with diminution or suppression of vision of the affected eye. Alterations

in this nerve are indicated on examination by a white, pearly atrophy of the optic papilla, which is accompanied in total atrophy by a mydriasis with suppression of the photomotor reflex. Lesions of the optic nerve occur in fractures of the orbital summit. Of the motor nerves the fourth cranial is rarely injured, while lesions of the third nerve are commoner. In the latter the paralysis is frequently total, involving the extrinsic and intrinsic branches. Sometimes only the extrinsic ones are involved, and occasionally only one filament, usually the nerve to the levator palpebrae superioris. Paralysis of the third nerve may be associated with paralysis of another oculomotor nerve, with atrophy of the optic nerve, or with facial paralysis. Lesions of this nerve occur in fractures involving the sphenoidal fissure, and are often incurable. The external oculomotor nerve (the sixth) is most frequently injured in cranial fractures, and usually affects it alone, or another motor nerve may be involved. The paralysis may be partial or total, and may disappear or persist definitely. Lesions of the sixth nerve are present in fractures of the petrous portion of the temporal bone. Involvement of the sympathetic nerves is exceptional; *it it occurs it causes the peculiar affection*, traumatic enophthalmia, which is almost always unilateral, and usually indicates a fracture of the orbital region.

361. Embryonal Carcinoma of Testis.

A. L. STAPLER (*Urol. and Cutan. Rev.*, July, 1929, p. 447), who records three illustrative cases in men aged 34, 40, and 22 respectively, with a review of the literature, states that testicular tumours form about 3 per cent. of all tumours. They generally occur between the ages of 18 and 40—that is, in the period of full sexual maturity. The great majority are malignant. Sarcoma of the testis is extremely rare, and most tumours of this origin are of carcinomatous nature. The great majority are of the nature of embryonal carcinoma—that is, a malignant epithelial tumour arising from heterologous tissues which establish its teratomatous nature—or spermatocytoma—that is, a malignant epithelial tumour arising from homologous elements (probably the seminiferous tubules), and morphologically different from tumours of teratomatous origin. Trauma is an important etiological factor, a history of it being present in 22 per cent. of Tanner's series. The principal symptoms are enlargement of the testis and neuralgic pain radiating to the abdomen and back. The skin over the enlarged testis may be unchanged or it may be reddened, hypervascular, or discoloured. Hydrocele is frequently present. Testicular tumour must be distinguished from tuberculosis, syphilis, and haematocele. The familial and personal history is of value in excluding tuberculosis and syphilis; tuberculous growth usually begins in the epididymis and extends later to the testicle, and other parts of the genital tract are likely to be affected. Haematocele can be excluded if the tunica vaginalis can be palpated on the surface of a scrotal tumour and if the epididymis can be felt on pinching. The prognosis of malignant tumours of the testicle is extremely bad. Of 600 cases collected by Tanner on which operation had been performed, only 5½ per cent. of those traced were alive and well after four and a half years. Treatment consists of removal of the affected testicle and retroperitoneal glands by the abdominal route, followed by the application of *x* rays and radium.

Therapeutics.

355. The Treatment of Hiccup.

G. ROSENFELD (*Med. Welt*, August 10th, 1929, p. 1152) thinks that hiccup is becoming increasingly prevalent; it is frequently associated with influenza, either as a prodromal symptom or as a sequel, and in rare cases it becomes chronic. The author asserts that chronic hiccup was formerly peculiar to Polish Jewesses, and was often very severe; latterly it has been of a milder type, and never occurs during sleep, although the condition may be very persistent. In one recent instance a young man suffered from persistent hiccup for three weeks. Rosenfeld has found treatment by suggestion and hypnosis very *satisfactory*. A Jewess who had very persistent hiccup was relieved during the preliminary procedures; hiccup ceased as soon as hypnosis was induced, and the patient had no recurrence. In another case the mere suggestion of treatment by hypnosis effected a cure. The old method of sipping water and then *holding* one's breath often *inhibits* the spasmodic contraction of the diaphragm. In other cases holding the nostrils and forcibly closing the lips until partial asphyxia occurs will relieve the condition. Rosenfeld has found that in some chronic cases good results follow the passage of an oesophageal bougie. The instrument is introduced into the stomach and is held in that position for several minutes until the patient attempts to breathe deeply. Although in the case previously mentioned of the young man in whom hiccup persisted for three weeks retention of the sound in the stomach for two minutes was followed by ten hours' remission, the paroxysms returned until the bougie was passed again and held *in situ* for ten minutes. This was followed by permanent cure. The author advises that the general health and nutrition of patients should be carefully regulated, especially when these are children. Some children suffer from hiccup when hungry or cold; barley sugar is recommended for them and the provision of warm clothing in winter. This treatment relieves the paroxysms and prevents recurrence. Finally, Rosenfeld refers to Benda's observation that severe hiccup is sometimes associated with epidemic encephalitis, as in the epidemics of 1921 and 1922.

356. Insulin in Pernicious Anaemia.

ANOREXIA is one of the characteristic symptoms of pernicious anaemia, and since insulin has been used effectively for this condition in other diseases, V. VARGA (*Paris Méd.*, September 21st, 1929, p. 249) has employed the drug in pernicious anaemia. Eight cases are reported in which its administration, either alone or with arsenic and liver extract, was followed, especially in one case, by striking benefits. Insulin produces astonishing results. Within three or four days hunger is strikingly manifested; simultaneously, the vertigo, tinnitus aurium, and general weakness disappear, and the skin and mucous membranes assume their normal colour. Headache is the last symptom to disappear, but the achlorhydria is uninfluenced. A marked improvement in the haematological picture is also observable. Walinsky and other authors consider that pernicious anaemia is the result of a blood acidosis, which favours haemolysis, and insulin is one of the best agents to combat this condition. The drug acts not only by suppressing the hormone disturbance and increasing the alkalinity of the blood, but also, by stimulating the appetite, it enables the organism to utilize the necessary aliments. As a commencing dose 30 units, gradually increased to 50, is administered in two doses half an hour before each chief meal. No signs of intolerance following these doses have been noted. The use of the liver extract, the "*hépatopson*" of Schottmüller, has, on account of its repugnant odour, been abandoned for the "perhépar" of Richter, a very condensed product in tablets, of which 1 gram corresponds to 100 grams of fresh liver. Varga considers that insulin is a most valuable adjunct to liver therapy, and that in grave cases in which, owing to the anorexia, the introduction of liver is difficult or impossible, it is indispensable.

357. Administration of the Barbituric Acid Derivatives.

S. WEISS (*Amer. Journ. Med. Sci.*, September, 1929, p. 390) agrees that the intravenous administration of the barbituric acid derivatives has a distinct therapeutic value, but he gives a warning that this method is not without danger if used indiscriminately. Many of the pharmacological and therapeutic actions are identical in all members of the series. The author discusses their pharmacological effects and toxicity in animals and men, together with their therapeutic uses in the latter, with more particular reference to sodium luminal (sodium-phenyl-ethyl barbiturate). He concludes that man is more susceptible to these drugs than animals, and that in human subjects a relatively smaller percentage of the fatal dose produces analgesia and narcosis. Marked individual variations exist in the response of patients to identical doses, and the state of the central nervous system is one of the important factors determ
Sensory and motor excitement act
depression acts synergistically with
derivatives. Sodium luminal injected intravenously in doses of 0.4 to 1.2 grams at a rate of 50 mg. per minute in a 10 per cent. solution stops convulsions, produces muscular relaxation, and induces sleep with considerable regularity. The narcosis may be superficial and the analgesia only partial. The effect of a single dose may last twelve hours. In certain patients with severe status epilepticus, eclampsia, grave toxic reactions from local anaesthetics, convulsions due to cerebral haemorrhage or tetanus, the intravenous injection of sodium luminal and other derivatives is of distinct value. The routine use of the intravenous hypnotic dose of these drugs for surgical anaesthesia, or for the inducement of sleep of long duration in certain psychoses, is held to be dangerous. The mechanism of the action of the barbituric acid derivatives is different from that of ether, chloroform, and nitrous oxide, and the latter cannot usually be replaced by the former. The hypnotics of the barbituric acid series have a marked inhibitory influence on certain medullary and mid-brain centres. The dose should be determined by the individual behaviour of the subject during the slow intravenous administration of the hypnotic. In the pathological conditions mentioned large sedative or hypnotic doses

should be given only if the condition of the patient is critical, and other efficient, and safer, measures are not available. A hypnotic dose of any of these derivatives entails potential danger for the patient.

368. Mercurial Inunction in Syphilis.

H. N. COLE, J. E. RAUSCHKOLB, N. E. SCHREIBER, and T. SOLLMANN (*Arch. Derm. and Syph.*, August, 1929, p. 176) report the results of a study to determine whether the absorption of mercury could be hastened materially and with safety by means of massive inunctions at weekly intervals. Six patients were selected, three with intact skins, two with papular syphiloderms, and one with a follicular syphilitic eruption. Massive inunctions of mild mercurial ointment in doses of 30 grams (*30 per cent. of mercury*) were rubbed into the skin for sixty minutes once a week for four weeks. The ointment was applied to the body generally, but especially to the chest, thighs, and forearms. These inunctions caused little or no irritation, and were quite as effective as the ordinary daily ones. A slight salivation was noted in but one case, and the condition of the teeth, if oral hygiene was followed, had little or no bearing on the appearance of salivation. Investigations of the excretory function showed a greater and more rapid cumulative removal of the mercury in the urine and faeces than with simple inunctions with 50 per cent. ointment, clean inunctions with 50 per cent. ointment (the excess of ointment being removed with benzene), simple inunctions with 25 per cent. *ointment, and daily intramuscular injections of mercuric* sodium bromide. The excretion of mercury in the after-period of four weeks was similar to that following daily inunctions. The authors believe, therefore, that this technique has practical advantages in the treatment of certain syphilitic patients requiring supervision by a physician.

Neurology and Psychology.

369. Infiltrating Cerebral Tumours.

THE diagnosis of cerebral disease is seldom easy if the course of events is rapid, and numerous unexpected complications arise; *it may be difficult to decide between cerebral tumour*, softening due to vascular thrombosis, and even some type of inflammatory disease. There may be a lack of the cardinal signs which would be expected to be present; the existing signs may, moreover, be misinterpreted and their importance wrongly assessed. H. L. PARKER (*Journ. Neurol. and Psychopath.*, July, 1929, p. 1) reports a case which illustrates these difficulties and indicates how cerebral tumours may affect the surrounding tissues. Without appreciable warning, progressive hemiplegia, aphasia, and stupor developed in a man aged 58, and death occurred within three weeks. A striking feature of the case was the presence of a turbid, greenish-yellow cerebro-spinal fluid, seemingly purulent. The turbidity was found to be due to an enormous number of polymorphonuclear leucocytes. There were 1,600 per c.mm. of these on the day of admission, and 107 small lymphocytes; on the

[illegible] cerebro-spinal fluid.

increased intracranial pressure, and a diagnosis of progressive thrombosis of the middle cerebral artery with wide infarction of the brain was made. That this was actually the case was shown by an exploratory craniotomy, but post-mortem examination revealed also the presence of a small tumour in the tip of the left temporal lobe. Presumably this had given rise to no symptoms until it had caused compression and thrombosis of the artery, with resultant softening of the brain. The difficulty of differentiating cerebral tumours and softening is well known, and Parker cites illustrative cases from the literature. A factor to be considered in the problem of associated tumour and softening is the character of the growth; in Parker's case this was a spongioblastoma multiforme, the one type of tumour usually associated with an acute onset, an extremely rapid development, and a brief clinical course terminating in death. The symptoms and findings in the case can be explained by the nature as well as the site of the neoplasm. The author finds the changes in the cerebro-spinal fluid harder to understand. Microscopically the walls of the ventricles showed in places masses of polymorphonuclear leucocytes, and he suggests that these represent a reaction of the tissues to the necrosis and softening. This occurred close to the ventricular cavity, and the cerebro-spinal fluid was necessarily flooded with these cellular products. Parker adds that support is thus

370. Treatment of Dementia Praecox.

K. SCHROEDER (*Ugeskrift for Laeger*, June 20th, 1929, p. 519) gives an account of six cases of dementia praecox treated with deep intramuscular injections of an emulsion of sublimed sulphur in olive oil. He states that in his cases of dementia paralytica this procedure has been even more effective than artificial infection with malaria. After giving details of these six cases, in which several injections were followed by the desired febrile reaction, the author mentions that the first three patients regained their capacity to work, the mental condition of one of them becoming perfectly normal. Of the remaining three patients, one became better but was lost sight of, another did not improve, and the third was so much benefited that he wished to return home and resume work. The author has persuaded two German colleagues to adopt this treatment, and the results they have achieved in about forty cases since they began this treatment in 1928 have been encouraging; in as many as sixteen there was more or less marked improvement in direct relation to t[illegible]hor further refers to investigations at [illegible]al in Lund, Sweden, by Dr. Loberg[illegible]rt's direction. The first preliminary [illegible] of fifty cases, is described as being so encouraging that further investigations on a large scale and with adequate controls are contemplated.

371. Psychoses Treated with Liver and Thyroid Extracts.

O. LINGJAERDE (*Nordisk Medicinsk Tidsskrift*, August 17th, 1929, p. 523), of the Dikemark Asylum in Norway, started his therapeutic investigations on the basis of Wigert's observation that in dementia praecox, running a comparatively favourable course the thyroid is slightly enlarged or at any rate definitely palpable, whereas in the cases running an unfavourable course this gland is not palpable. The basal metabolism being the best index to the functional condition of the thyroid, the author has investigated the basal metabolism in about 130 cases, and he has never found it above normal in any case of schizophrenia. Many attempts to treat this condition with thyroid extracts have been made, and the author suggests that many of the failures have been due to inadequate dosage. Using the Norwegian thyroid preparation "nyco," standardized by the aceto-nitril method, each tablet corresponding in action to 0.10 mg. of pure thyroxin, and containing the equivalent of 0.30 gram of the fresh gland, he has exceeded the timid dosage of one or two tablets a day, and has pushed the treatment till the basal metabolism was over 110–115, and the pulse rate had risen to 80–100, at which stage he has ke[illegible] several months. Among 20 ca[illegible] there were 8 in which grea[illegible] symptoms was achieved, [illegible] improvement. In May, [illegible] with a diet of liver in certain cases, but on this treatment alone the improvement observed was limited to the purely physical condition of the patients; very good results were obtained, however, *in some cases with a combination of thyroid and* liver treatment, 9 out of 13 cases of schizophrenia showing great improvement or freedom from symptoms, and 2 other patients being markedly benefited. The author does not claim that these substances act as a specific on a well-defined morbid entity, but he believes they may support the body's natural recuperative powers.

Obstetrics and Gynaecology.

372. Transplantation of the Ovaries.

SERDUKOFF (*La Gynécol.*, June, 1929, p. 321) remarks that, with the development of endocrinology, transplantation of tissues and glands has assumed an important place in practical medicine; he discusses ovarian transplantation as to its indications, technique, and results. The operation consists of either auto-, homo-, or hetero-transplantation, or the transplantation of tissues of an animal of the same type and species. According to him, the best material for transplantation is that taken from goats or monkeys; very rarely are auto- or homo-transplants successful. One of the following methods can be employed: (1) a procedure which leaves intact the neuro-vascular pedicle of the transplant; (2) the implantation of the vessels of the transplant—a difficult method; (3) the transplantation of the glands after their section into small pieces; (4) after their division into only two portions. Serdukoff advocates the last method, and describes his operative technique. He reports his results in forty cases, and asserts that, by transplantation of the endocrine glands, the equilibrium of the endocrine status can be reconstituted and the fundamental functions of the female organism be regulated. Simultaneous transplantation

of the ovary, anterior lobe of the pituitary body, and thyroid gland gives better results than that of the ovary alone. In cases of infantile genital organs, ovarian transplantation plays a stimulating, trophic role, contributing to a duplication of the blood supply, to an increase of the uterus, and to a care of the functional form of sterility. In cases of amenorrhoea in castrated females, transplantation of the endometrium must be performed simultaneously with that of the endocrine glands. Success in transplantation strictly depends on an exact diagnosis and on well-marked individual indications.

373. Inflammatory Tumours of the Uterine Appendages.

ACCORDING to H. KIENLIN (*Zentralbl. f. Gynäk.*, July 13th, 1929, p. 1775) the main causes of such tumours are gonococcal infection, pregnancy, necrotic tumours, and tuberculosis. Hydrosalpinx has been caused in animal experiments by closure of the abdominal end of the tube, and a similar condition may arise in the human subject in cases of fibroid where adhesions blocking the abdominal ostium have been caused by friction of the tumour mass. Adhesions arising from endometritis may cause hydrosalpinx or haematosalpinx, and organisms may reach the tube in the menstrual blood. Infection by the blood stream is also possible. To elucidate this question 60 uteri excised at operation have been investigated bacteriologically, especially in regard to anaerobic organisms; the organs were removed under sterile precautions, and swabs were taken immediately after removal from the body, isthmus, and cervix, and cultured on bouillon, grape sugar and blood agar, and on blood. From these cases the following deductions have been made. The uterine cavity remains sterile even after prolonged haemorrhages. In isolated cases a few pyogenic organisms are found, and in such cases infection of the appendages is possible if any of the uterine contents pass into the tube; this may happen where there is any obstruction to the outflow by the vagina. It is therefore possible to find infective tumours without any of the above recognized causes; and this is commonest in elderly women, where the mucous membrane is inactive, cervical stenosis is approaching, and the outflow is slowed.

374. Painful Relaxation of Pelvic Joints in Pregnancy.

K. SKAJA (*Norsk Mag. f. Laegevid.*, July, 1929, p. 728) found painful relaxation of the symphysis and sacro-iliac joints in 31 out of 185 private patients (16.8 per cent.) at the end of pregnancy. In a number of instances these symptoms were only slight, but in one case after the pain had increased for some time rupture of the symphysis occurred when the patient turned in bed. Another three cases showed symptoms of rupture, which was not confirmed by *x*-ray examination. Two patients had pain and difficulty in walking, which recurred and increased with each pregnancy, from affection of one sacro-iliac joint. *X* ray examination was performed in 35 patients without, and 13 patients with, painful relaxation of the joints during pregnancy. A new technique was employed, the Roentgen film being placed in the vagina just behind the symphysis. The width of the symphysis in both groups was from 4 to 9 mm. In the second group cavity formation in the cartilage was far more frequent, while in some cases there were patches of atrophy in the adjacent part of the pubic bone.

375. Syphilis and Pregnancy.

A. S. WELLS (*Journ. Med. Assoc. South Africa*, June, 1929, p. 331) states that in 1,000 women whose blood was examined during pregnancy, a positive Wassermann reaction was obtained in 28.2 per cent.; placental blood examined in 393 cases proved positive in 23.5 per cent. These figures are high when compared with those of Edinburgh, Glasgow, and Copenhagen, where a positive Wassermann reaction is found in from 5 to 7 per cent. of pregnant women. Wells points out that a negative Wassermann reaction may occur when syphilis is present, but, according to Adams, the test is reliable in all but 1 to 3 per cent. of cases. As regards the significance of testing the placental blood, the chorionic ferments have the power of preventing the infection passing to the child (Adams); Wells remarks that, if this is so, then the results obtained in his series are high. The reactions of the male and female to syphilis are compared. In the female the chancre is rarely seen; rather is there a granulomatous infiltration of the uterus and cervix. The vaginal portion of the latter is indurated and discoloured; it is often cauliflowerlike in appearance, with a similar change evident in the urethral meatus, clitoris, and breast nipple. The symptoms of secondary syphilis are milder in women than in men, but a marked constitutional disturbance is much more often present. This difference is still without explanation. It may be that the serums are different—that in the female there is a greater lymphocytosis; or, again, it may be that a protective action is produced by some hormone, or that a conceptional protection results through chorionic proteins.

Treatment is usually satisfactory, according to Wells, if begun six weeks before term. Weekly injections of novarsenobillon intravenously and bismuth intramuscularly are given, while cases admitted just before, or in, labour have intravenous injections of novarsenobillon if no albuminuria is present, with a view to reducing the risk of infection to both nurses and child.

Pathology.

376. Filterable Forms of the Tubercle Bacillus.

S. R. GLOYNE, R. E. GLOVER, and A. S. GRIFFITH (*Journ. Path. and Bact.*, October, 1929, p. 775) have conducted in London and Cambridge a series of experiments to determine whether it is possible to demonstrate the existence of a filterable form of the tubercle bacillus. These experiments conformed in their general plan to those described by French workers during the past few years; special care, however, was taken over technique. Doubtful lesions in the inoculated animals were closely scrutinized, and in most cases examined both histologically and by animal passage. The material examined comprised tuberculous sputum, which was generally used either fresh or after three days' autolysis in the incubator; placental or foetal tissues from tuberculous mothers; the organs of naturally or experimentally infected rabbits, guinea-pigs, or fowls; and cultures of human, bovine, and avian types. From this material suspensions were prepared in saline solution or broth. After preliminary centrifugalization or coarse filtration, these suspensions were passed through Chamberland L_2 or L_3 candles, or in a few instances through a Berkefeld N candle. The pressures employed in filtration were 150 to 200 mm. of mercury in one series of experiments, and 500 mm. in another. The filtrates were injected into guinea-pigs in the case of mammalian, and into fowls in the case of avian viruses. The dose used varied from 1 to 5 c.cm. in one series, and from 5.5 to 40 c.cm. in another. The results of these experiments were entirely negative. None of the animals inoculated showed any of the usual signs of tuberculosis, even though they were not killed as a rule for three or four months. A few of the animals died, generally from pseudo-tuberculosis or a staphylococcal infection. None of the passage animals inoculated from doubtful lesions showed any signs of tuberculosis. These experiments have therefore failed to demonstrate the existence of a filterable form of the tubercle bacillus.

377. Persistence of Living Cells in Maitland's Medium for Cultivating Vaccine Virus.

T. M. RIVERS, E. HAAGEN, and R. S. MUCKENFUSS (*Journ. Exper. Med.*, August, 1929, p. 181) have repeated the experiments of the Maitlands on the cultivation of vaccinia virus in a medium that was supposed to be unsuitable for the multiplication of the tissue cells. This medium consisted of minced chicken kidney suspended in a mixture of chicken serum (1 part) and Tyrode's solution (2 parts). It was found by the Maitlands that vaccinia virus multiplied abundantly in this medium, and they were of the opinion that this multiplication occurred in the absence of growth of tissue cells. The present authors have confirmed the increase of the vaccinia virus, but from experiments devised to determine the length of time that living cells might survive under these conditions they come to the conclusion that this medium must be regarded as in fact a tissue culture. By subculture into suitable media they obtained evidence that many cells were able to remain viable in it for at least five days. It was found, moreover, that a medium of serum and Tyrode's solution was capable at times of supporting multiplication of certain cells. It would appear, therefore, that the increase of vaccine virus in this medium does not occur in the absence of living cells. In support of this statement they find that if the chicken kidney is frozen and thawed an adequate number of times, so that subcultures into favourable media prove negative, showing that the cells are in all probability destroyed, no multiplication of the vaccinia virus occurs.

378. Relation between the Thyroid and the Tonsils.

G. BUSACCA (*Arch. Ital. di Otol., Rinol. e Laryngol.*, August, 1929, p. 519), in order to determine the relation existing between the thyroid gland and the tonsils, carried out experiments on young dogs, with the following results. Total thyroparathyroidectomy produced changes in the tonsils consisting in a slight diminution of weight of the organs, and, histologically, in a decrease in number and still more in size of the follicles, with a consequent relative increase in the adenoid tissue, diminution of the lymphoid cells, and an increase in the cells of the reticulum. On the other hand, partial thyroidectomy did not cause any appreciable changes in the structure of the tonsils.

CONCEALED CONSTIPATION

HALF the constipation in the world is never recognized. So long as some measure of intestinal elimination occurs daily, it is commonly assumed that in this department of physiology all is well. Yet the degree of *concealed* constipation may be pronounced, and the large bowel may never be properly evacuated. A vicious circle is thus set up, and the intestinal musculature becomes diminishingly responsive and progressively atonic.

The functional interrelation of the body's whole eliminatory chain is such that intestinal stagnation causes a general hold-up of the scavenging processes even in the remotest tissues. It is probably thus, rather than through direct absorption of toxins from the intestines, that most of the unpleasant symptoms of constipation—headache, malaise, lassitude, etc.—are produced. It is surprising how promptly and completely these symptoms are cleared up by a regular morning glass of Eno's "Fruit Salt" taken before the early cup of tea.

As is generally known among medical men, Eno's "Fruit Salt" is a carefully blended combination of alkalies with fruit acids, and is absolutely free from such nauseating mineral purgative salts as the sulphates of soda and magnesia. It contains no sugar or added flavouring agents, its palatableness being due to its physical texture and the uniform solubility of its graded particles.

"The Doctor's Emergency Reminder."

The Proprietors of Eno's "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest addition to their series of "Medical Reminders"—with or without a bottle of their preparation (Handy or Household size as required). "THE DOCTOR'S EMERGENCY REMINDER" summarises briefly a few points in connection with the treatment of poisoning and various other emergency cases. It is bound in black morocco limp to conform to the style of the previous publications in this series.

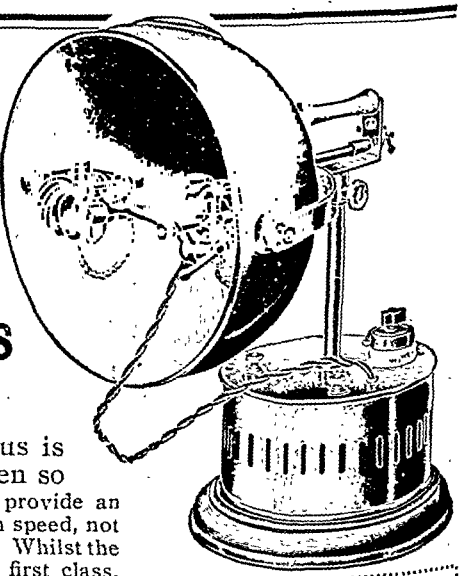
THOUSANDS OF TREATMENTS ARE ADMINISTERED DAILY

"MEDISUN"

ULTRA-VIOLET LIGHT APPARATUS

100% BRITISH.



Specification:

The "MEDISUN" Ultra-Violet Light Apparatus is of the quartz mercury vapour type. It has been so designed as to eliminate all unnecessary expense, and yet provide an efficient source of ultra-violet radiation, quick in its reaction speed, not requiring adjustment, and foolproof in its mechanical details. Whilst the price of the "Medisun" is quite low, its appearance is really first class. Manufactured in polished aluminium throughout, it does not require frequent cleaning, is designed to stand on any table, weighs only 14 lb., and is a thoroughly reliable piece of apparatus.

RUNNING COST: **30 TREATMENTS 3d.**

Price:
For use on Direct Current ... £12
For use on Alternating Current £18
THIRTY OTHER TYPES

Lounge Suits *for* Doctors

£1 PER MONTH

Appearance is everything to the professional man, as nothing enhances status so much as good attire.

Most tailors study price, fit and finish, but few care what happens to your clothes after purchase, whereas Keith Bradbury Ltd. provide a FREE VALET SERVICE for the care of their customers' clothes after purchase; garments are collected, brushed, repaired, sponged, pressed and returned like new.

Every consideration is given to the financial convenience of Doctors, who, more often than not, have to wait indefinitely for settlement of their own accounts. Arrangements are made whereby accounts can be disposed of half-yearly, quarterly, upon a £1 a month basis, or in any other way to suit individual requirements.

Distance need be no barrier to country practitioners, as the comprehensive Keith Bradbury self-measurement chart assures a perfect fit of all West End garments supplied by post—and to convince you that our confidence in this through-the-post service is not misplaced, we undertake to give you complete satisfaction or re-make the garments ordered.

An illustrated catalogue, patterns or full particulars of our special financial facilities will be gladly sent upon receipt of a postcard or telephone message, or, perhaps you prefer to call and see us.

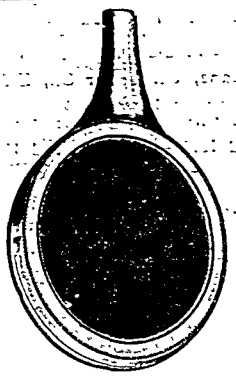
JOHN WARD Ltd

242-7 Tottenham Ct. Rd. London



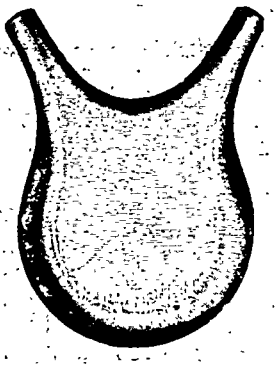
MINCHIN'S CHESTPIECES

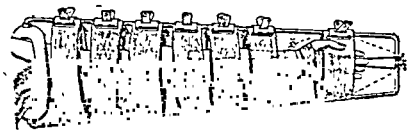
(REGISTERED)

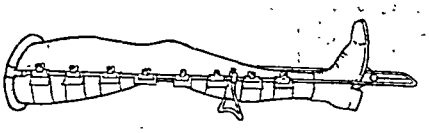
For Single and Binaural Stethoscopes.

Being set at right angles to those in general use afford the following advantages: Time is saved, as little undressing is necessary. Bed patients can be examined without disturbance. The heart can be examined whilst patient lies face down, with the result that sounds are much more distinct. This also applies to the Fœtal Heart. Children can be more readily examined by this Chestpiece than by the older patterns as it is not necessary to stand in front of them. Also made with attachment for use with Sphygmometer.

To be obtained from all Surgical Instrument Makers.







COLLENDER'S SPLINTS

(Patented in the Leading Countries of the World)

An evolution of the Thomas Splint—all the advantages of the Thomas Splint are preserved, with many important improvements, additions, and modifications.
They are supplied in strong fitted case, and enable 10 fractures simultaneously to be put up in any position obtainable by Thomas arm or leg Splints.
They provide the most modern methods of accurate extension, and safe transport of the patient is assured. Complete splints suited to limbs of any dimensions can be constructed in a few minutes from the component parts.

All members are interchangeable, standardised, numbered, and replaceable. They are made of Duralumin, which is untarnishable, exceedingly light in weight, and of great tensile strength. They can be immersed in sterilizing fluid without injury and can be used repeatedly.
Collender's Splints will be found invaluable for Hospital Emergency work and particularly to District Surgeons, Mines, Ranches, Lumber Camps, Railways, Shipping Companies, Industrial Plants, and all places remote from surgical help.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: The Most Hon. the Marquess of Exeter, C.M.G., A.D.C.

Medical Superintendent: Daniel F. Rambaut, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facilitiy for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

REPRESENTATIVE ON THE GENERAL MEDICAL COUNCIL:
ALEXANDER MILES, M.D., LL.D.

The Royal Society.

FOULERTON RESEARCH STUDENTSHIP.

Subject to candidates of sufficient merit presenting themselves, the President and Council of the Royal Society propose to appoint a Foulerton Research Student at a stipend of £700 per annum, the duties of the Student being to conduct researches in Medicine or the contributory sciences under the supervision and control of the Management Committee, to whom he will be required to report from time to time.

The Studentship will be tenable for three years, but may be renewed from year to year with a maximal total tenure of six years. Members of either sex are equally eligible, but must be of British nationality. Applications must reach the Royal Society not later than December 9th. Further particulars can be obtained from the Assistant Secretary of the Royal Society, Burlington House, London, W.1.

George Henry Lewes Studentship
IN PHYSIOLOGY.
ANNUAL VALUE £250 (about).

The Student is required to give his whole time to research work except such as, in the opinion of the Trustees, does not interfere with his original enquiries. Candidates should send (*a*) a statement of their qualifications, (*b*) the subject of their proposed research, (*c*) the name of one referee to the Director, Prof BARCROFT, Physiology School, Cambridge, by Nov. 15th.

The studentship is open to persons of either sex and is tenable for one, two, or three years as the Trustees shall decide. The student is expected to work in the Cambridge Physiology School, but under special circumstances with the consent of the Director he may carry on his researches elsewhere.

The Middlesex Hospital and MEDICAL SCHOOL, W.1.

Applications are invited for ONE MEDICAL and ONE SURGICAL REGISTRARSHIP. The Registrars are attached to Clinical Units of the Hospital and are responsible for the clinical notes, the carrying out of clinical and pathological examinations, the preparation of material for demonstration, and the co-ordination of the work in the Bland-Sutton Institute of Pathology with that in the Wards.

The appointment is for one year from January 1st, 1930, and the holder is eligible to apply for re-appointment, and may retain office for three consecutive years. Salary £300 per annum. He is required to attend at the Hospital daily from 10 to 5. Further particulars may be obtained from the Secretary-Superintendent, to whom applications, with not more than three testimonials, must be sent by noon on Tuesday, December 10th.

By Order of the Board,
S. R. C. PLIMSOLL, Secretary-Supt.

ROYAL NAVAL DENTAL SERVICE.

The Admiralty is prepared to receive applications from qualified Dental Surgeons for entry into the Royal Navy as DENTAL OFFICERS.

Two vacancies are to be filled. Candidates must be below 28 years of age on December 31st, 1929 (unless granted an allowance for age, not exceeding six months, in respect of a period served in a recognized Civil Hospital appointment), and must be registered under the Dentists Act as qualified to practise as Dental Surgeons in Great Britain and Ireland. They will be required to appear before a Selection Committee and to pass a medical examination by a Board of Naval Medical Officers as to their physical fitness for entry.

The Regulations for entry and the forms to be filled up by candidates can be obtained on application to the Medical Director General of the Navy, Queen Anne's Chambers, Tothill Street, London, S.W.1.

The form of application, accompanied by the necessary documents, must reach the Medical Director General not later than November 18th.

The University of Adelaide.

ELDER PROFESSOR OF ANATOMY AND HISTOLOGY.

Applications are invited for the Elder Professorship of Anatomy and Histology in the University of Adelaide, South Australia.

The Professor will be required to offer courses of lectures and practical work in Anatomy and Histology suitable for students in Medicine and in Dentistry, together with advanced courses suitable for Honours students in Science.

The services of a full-time lecturer are provided and also a technician. Salary £1,100 per annum.

Applications, with testimonials, statement of age, academic qualifications, experience, and copies of publications, should reach the Registrar, the University of Adelaide, South Australia, not later than January 1st, 1930. Candidates must state the earliest date after March 1st at which they can take up their duties.

Further information may be obtained from:
(*a*) The Agent-General for South Australia, Australia House, Strand, London.
(*b*) Any University in Australia or New Zealand.

F. W. EARDLEY, Registrar.

The University of Sheffield.

Applications are invited from Graduates of the University of London in Medicine and Surgery for the GEOFFREY DUVEEN TRAVELLING STUDENTSHIP IN OTO-RHINO-LARYNGOLOGY, which is of the value of £450 a year, and is tenable, in the first instance, for one year.

Applications should reach the University on or be[illegible] must be made on the [illegible] may be obtained, toget[illegible]ulars, from the Acad[illegible] of London, South Kensington, S.W.7.

The Royal Infirmary,
SUNDERLAND. (290 Beds.)

Wanted beginning of December, HOUSE PHYSICIAN (male). Salary £140 per annum, with board, residence, and laundry.

Applications, stating age, qualifications, and accompanied by copies of testimonials, to be sent to the undersigned by October 18th.

S. C. FRYERS,
House Governor and Secretary.

County Borough of Dewsbury.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER.

The Dewsbury Corporation invite applications from duly qualified and registered Medical Practitioners holding the Diploma in Public Health for the position of Medical Officer of Health and School Medical Officer at a commencing salary of £900 per annum.

The gentleman appointed will be required to devote the whole of his time to the duties of the office, to reside in the Borough, and will not be allowed to engage in private practice. All emoluments or fees which may be payable to, or received by him, must be paid over to the Corporation.

The appointment will be made in accordance with and subject to the Public Health Officers Act, 1921, the Sanitary Officers Order, 1926, and to the approval of the Minister of Health.

Canvassing, either directly or indirectly, is prohibited. Applicants may, if they desire, forward 15 copies of their application and testimonials for the use of the members of the Committee.

Applications, with copies of not more than three recent testimonials attached, to be sent to me, endorsed "Medical Officer of Health," not later than November 8th.

HOLLAND BOOTH,
Town Clerk.

Town Hall,
Dewsbury.
October 16th, 1929.

Leicestershire County Council.

ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified Medical Practitioners (male) under 40 years of age, for the appointment of Assistant County Medical Officer.

Candidates must possess a Diploma in Public Health; experience in School Medical Inspection and Public Health administration will be deemed additional qualifications.

The person appointed must devote the whole of his time to the duties of the office, and will carry out such other duties as the County Medical Officer may assign to him.

The salary will be at the rate of £650 per annum, rising, subject to satisfactory service, by annual increments of £25 to £700 per annum, with travelling expenses according to the County Council scale.

The appointment is subject to the Local Government and Other Officers Superannuation Act, 1922.

The appointment will be terminable by three months' notice on either side.

Forms of application may be obtained from the undersigned, and should be returned, accompanied by copies of not more than three recent testimonials, by Friday, November 1st.

W. J. FREER,
Clerk to the Council.

10, New Street,
Leicester.
October 14th, 1929.

City of Birmingham.

MEDICAL OFFICER FOR MATERNITY AND CHILD WELFARE.

The Public Health Committee invite applications from Medical Women for the post of Medical Officer for Maternity and Child Welfare. Applicants must have had Children's Hospital and Maternity Hospital experience. The Diploma of Public Health is desirable. Salary £600 per annum. The candidate appointed will be required to join the Birmingham Corporation Superannuation Scheme, and for this purpose to pass a medical examination. The appointment will be terminated by one month's notice on either side. Applications endorsed "Medical Officer for Maternity and Child Welfare," and accompanied by copies of three recent testimonials, to be made on a form to be obtained from the Medical Officer of Health, Council House, Birmingham, and returned to him on or before November 2nd. Canvassing will disqualify.

Borough of Dover.

ASSISTANT MEDICAL OFFICER OF HEALTH.

The Corporation of Dover invite applications for the above appointment from Medical Practitioners between 30 and 40 years of age who hold a Diploma in Sanitary Science. Salary £700, rising to £750.

The applicant appointed will be required to commence his duties as soon as possible and to devote his attention principally to work under the Aliens Order, 1920. Colloquial French and German will be a recommendation.

Further details of the duties and terms and conditions of the appointment may be obtained of the undersigned, to whom applications, accompanied by copies of testimonials, must be delivered by November 4th.

R. E. KNOCKER,
Town Clerk.

Town Clerk's Office,
Brook House, Dover.
October 15th, 1929.

ROYAL NAVAL MEDICAL SERVICE.

VACANCIES EXIST FOR MEDICAL OFFICERS IN THE ROYAL NAVY.

Candidates will be entered as Short Service Medical Officers and will be considered for transfer to the Permanent Service after 6 months' service. They must be registered under the Medical Acts, and be under 30 years of age on date of entry.

Medical Officers, R.N., are liable to serve in Naval Hospitals or Ships in any part of the world.

Excellent opportunities exist for clinical professional work, both medical and surgical, as well as for study and practice of Hygiene, Pathology, Ophthalmology, and other specialist branches.

Adequate provision is made for Post-Graduate Study.

OUTFIT ALLOWANCE of £50 is paid on joining.

PAY.—Pay from £452 to £2,350 a year, according to length of service.

ALLOWANCES.—When in charge of **Hospitals** and **Sick Quarters,** 10s. and 5s. a day.

60 Specialists Allowances of 5s. a day.
Flag Allowances, 5s. and 2s. 6d. a day.
Provision Allowance, Lodging Allowance, etc.

PROMOTION.—To Surgeon Lieutenant Commander after 6 years' service; to Surgeon Commander after a total of 12 years' service. Promotion to Surgeon Captain, Surgeon Rear-Admiral, and Surgeon Vice-Admiral is by selection.

Ante-date of seniority on account of civil hospital appointments, and accelerated promotion can be gained.

RETIREMENT.—Gratuities are paid as follows:—

Short Service Officers, after 3 years' service	£300
Permanent Officers, after 4 years' service ...	£400
,, 8 ,, ,, ...	£1,000
,, 12 ,, ,, ...	£1,500
,, 18 ,, ,, ...	£2,250

Rates of Pension range from £423 a year, normally earned after 20 years' service, to £1,123 a year, the maximum earned by a Surgeon Vice-Admiral.

Copies of the Regulations and Particulars as to Conditions of Service and Emoluments may be obtained on written or personal application to the Medical Director General of the Navy, Queen Anne's Chambers, Tothill Street, London, S.W.1.

City of Plymouth.

MATERNITY AND CHILD WELFARE DEPT.

ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified Medical Women for the position of Assistant Medical Officer of Health in the Maternity and Child Welfare Department of the City. The person appointed will rank as an Assistant Medical Officer of Health, and will work under the direction of the Medical Officer of Health.

Candidates must have had practical experience in Maternity and Child Welfare work, and preference will be given to those who have had special experience in the Diseases of Children and Women, in Venereal Diseases, and in Ultra-violet Light Therapy.

The person appointed will be required to devote the whole of her time to the duties of the office, and will not be allowed to engage in private or consulting practice. The appointment will be terminable by three months' notice, in writing, on either side. The salary is at the rate of £600 per annum.

Applications, stating age, qualifications, and experience, together with copies of not more than three recent testimonials, should be sent to the undersigned not later than Saturday, November 2nd, and should be endorsed "Assistant Medical Officer." Forms of application will not be provided. Canvassing will be a disqualification.

A. T. NANKIVELL, M.D., M.R.C.P., D.P.H.,
Town Hall, Medical Officer of
Stonehouse, Plymouth. Health.
October 16th, 1929.

City and County of Kingston-upon-Hull.

ASSISTANT MEDICAL OFFICER OF HEALTH.

The Corporation of Hull invite applications from Medical Men, under the age of 40 years, and of not less than three years' standing in their profession, for the post of Assistant Medical Officer of Health.

Salary £600 per annum, rising by annual increments of £25 to £700.

The appointment is subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

The successful candidate will be required to devote the whole of his time to the duties of the office, which consists mainly of work in the School Medical Department, but may also include duty in any section of the Health Services of the City or Port.

A form of application may be obtained from the undersigned, and must be returned to the Medical Officer of Health (in an envelope, endorsed "Assistant Medical Officer of Health"), together with copies of three recent testimonials, not later than the first post on Thursday, November 7th.

Health Department, W. ALLEN DALEY,
Guildhall, Hull. Medical Officer of
Oct. 12th, 1929. Health.

Sheffield City Hospitals.

INFECTIOUS DISEASES.
(537 Beds)

RESIDENT MEDICAL OFFICER.

Applications are invited from duly qualified registered Medical Practitioners with Bacteriological experience for the post of Resident Medical Officer (male).

Salary, with three years' experience in professional practice, £350, with board, lodging, and washing.

Applications, stating age, qualifications, and previous experience, together with copies of recent testimonials, to be sent to the Medical Superintendent, Lodge Moor Hospital, Sheffield, not later than November 1st.

County Borough of East Ham.

MEDICAL
RESIDENT
ISOLATION

The Town Council invite applications from duly qualified persons for the appointment of Deputy Medical Officer of Health and Resident Medical Superintendent of the Isolation Hospital at a salary of £700 per annum, plus residence, light, and fuel (these emoluments being valued for superannuation purposes at £100 per annum).

Age not to exceed 45 years.

The successful candidate will be required to give full-time service and act under the control and direction of the Medical Officer of Health. Administrative and organising ability are essential qualifications for the post.

Candidates must possess the Diploma in Public Health and must have had previous experience of administration in a Public Health Department of a Municipal Corporation.

The appointment will be subject to the approval of the Ministry of Health and the Board of Education.

The person appointed must not engage in private practice, and will be required to pass a medical examination, and the appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Applications, on forms to be obtained from the undersigned, must be, together with copies of three recent testimonials, received by him on or before noon on Thursday, November 14th.

Canvassing, either directly or indirectly, will disqualify.

By Order,
Town Hall, C. EUSTACE WILSON,
East Ham, E.6. Town Clerk.
October 16th, 1929.

Liverpool County Borough.

LOCAL EDUCATION AUTHORITY.

JUNIOR ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited for a JUNIOR ASSISTANT SCHOOL MEDICAL OFFICER in the Department of the Medical Officer to the Local Education Authority, at a salary of £600 per annum.

Applicants must be registered Medical Practitioners, and shall have had at least three years' experience. It is desirable that they should have had some special experience in School Hygiene and in Diseases of Children.

The officer appointed will be required to devote his whole time to the service of the Education Authority, under the direction of the Medical Officer to the Education Authority. He will not be allowed to undertake private practice, and will be required to contribute to the Liverpool Corporation Superannuation Scheme, as required by the Standing Orders of the City Council.

A form of application may be obtained from the undersigned, and applications, endorsed "Junior Assistant School Medical Officer," must be delivered at the office of the Town Clerk, Municipal Buildings, Liverpool, on or before November 4th.

Canvassing of members of the Committee or the City Council is strictly prohibited, and will be considered a disqualification.

J. M. SHEPPARD, F.C.I.S.,
Secretary.

Brighton Parish.

SENIOR ASSISTANT (RESIDENT) MEDICAL OFFICER.

The Guardians of the Poor of the above-named Parish require the services of a Senior Assistant *(Resident)* Medical Officer at their Poor Law Infirmary.

Candidates must be single men under the age of 35 years.

The appointment is for one year only, but the person appointed will be eligible for further appointment from year to year.

The Infirmary has a consulting staff and is divided into Medical, Surgical, and Gynæcological and Obstetrical, etc., sections; there are also X-ray, Electro-therapeutic and Massage Departments.

The person appointed must be duly registered and in possession of the qualifications required by the Minister of Health. Experience in the management and routine work of a Hospital is essential. He will be required to devote the whole of his time to the service of the Guardians and to act as Deputy to the Medical Officer both at the Poor Law Institution and Warren Farm (Poor Law) Schools, which are situate about two miles from the Infirmary, and containing approximately 250 children; he will also carry out such other duties as may be assigned to him by the Medical Officer.

Salary £375 per annum, with residential allowances valued for the purposes of the Poor Law Officers Superannuation Act, 1895, at £150 per annum.

Applications for the appointment, giving age, qualifications, etc., accompanied by copies of not more than three recent testimonials, and a description of the diplomas, certificates of degrees, licences, and other instruments held by the candidate, must be sent to me not later than Monday, November 4th, by 10 o'clock in the forenoon.

Further particulars of the appointment may be obtained on application to the Medical Officer of the Infirmary.

By Order,
Poor Law Offices, HORACE BURFIELD,
Prince's St., Brighton. Clerk to the
October 21st, 1929. Guardians.

Brighton Parish.

APPOINTMENT OF ANÆSTHETIST.

The Guardians of the Poor of the above-named Parish invite applications from duly qualified Medical Practitioners for the appointment of Anæsthetist at the Poor Law Institution Infirmary, Elm Grove, Brighton.

Salary 150 guineas per annum.

The appointment will be subject to the provisions of the Poor Law Officers Superannuation Act, 1895.

The person appointed will be required to administer anæsthetics at the Poor Law Infirmary at the request of the Medical Officer or his Deputy, and to provide at his own expense a duly qualified Medical Practitioner to act as Deputy Anæsthetist during any period of holiday or absence from duty.

Applications for the appointment, giving age, qualifications, etc., and stating what experience the candidate has had in administering anæsthetics, accompanied by not more than three recent testimonials, must be sent to me not later than 10 o'clock in the forenoon of Monday, November 4th.

Further particulars, if desired, may be obtained from Mr. H. J. [illegible], M.S.(Eng.), Medical Officer of the Poor Law Institution.

Canvassing the Guardians, either personally or by letter, will be considered a disqualification.

By Order,
Poor Law Offices, HORACE BURFIELD,
Prince's St., Brighton. Clerk to the
October 21st, 1929. Guardians.

PNEUMONIA

TRANSPULMIN

A sterile solution of basic quinine and camphor in etheral oils. Provides the first painless method of injecting quinine in the treatment of

BRONCHITIS **PNEUMONIA** **BRONCHIECTASIS**

Especially useful for the prevention and treatment of pulmonary complications in Influenza, and in the treatment of Asthma.

It has been found in hospital practice that Transpulmin gives more relief in long-standing cases of emphysema than any other form of treatment.

In more than 1,000 cases of Pneumonia in hospital the mortality rate with Transpulmin was *less than half* that prevailing where other methods were used.

In ampoules of 1.2 c.c. and bottles of 25 c.c.

Literature and Clinical Sample on application.

WHOOPING COUGH.

To control quickly the spasmodic coughing and vomiting, use the original ELIXIR of EPHEDRINE (Abbott)

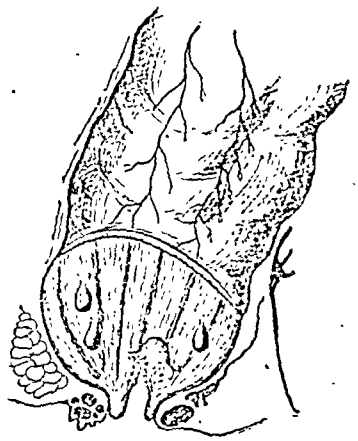
The Haemorrhoidal Circle



Internal and external hæmorrhoids resulting from pressure upon the blood vessels and obstruction of the circulation in the rectum.

DISTENTION of the rectum from painful defæcation—pressure on the rectal blood vessels — impeded circulation — hæmorrhoids. Cathartics to relieve the constipation —irritation of the mucous membrane and the existing hæmorrhoids — pain — possible anal fissure — cessation of purging—constipation.

Such is all too frequently the vicious circle of dyschezia and hæmorrhoids, a combination which requires appropriate local treatment and a bowel corrective that will not irritate.

AGAROL Brand Compound, the original emulsion of mineral oil, agar-agar and phenolphthalein, is pre-eminently indicated for the correction of the vicious circle.

AGAROL Brand Compound lubricates, therefore prevents irritation by friction; it segments and softens the fæcal mass, and thereby prevents possible excessive strain in the expulsion of it; it stimulates the peristaltic force without the shock of cathartics.

A liberal quantity sent to physicians on request.

FRANCIS NEWBERY & SONS, LTD.
31-33, BANNER STREET,
LONDON, E.C.1

Prepared by WILLIAM R. WARNER & CO., INC.
Manufacturing Pharmacists Since 1856

Agarol Brand Compound is the *original* Mineral Oil—Agar-Agar Emulsion (with Phenolphthalein) and has these advantages:
Perfect emulsification; stability; pleasant taste without artificial flavouring; free from sugar, alkalies and alcohol; no oil leakage; no griping or pain; no nausea; not habit forming.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

In the Insulin Treatment of Diabetes the diet is still a factor of vital importance.

'Allenburys' Diabetic Flour

Is a special preparation of caseins and lactalbumen to which leavening agents are added.

It is a satisfactory and convenient product for the preparation of special foods, free from carbohydrates, and containing a minimum of fat; or definite proportions of these may be added as tolerance increases with the progress of the treatment. The 'Allenburys' Diabetic Flour is compact, convenient to use, and keeps well. From it may be prepared a variety of palatable and highly nutritious foods of special composition. Recipes and directions for use are enclosed with each packet.

COMPOSITION:	Per cent.
SPECIAL CASEIN	87.0
FAT	0.7
SODIUM BICARBONATE	1.6
ACID POTASSIUM TARTRATE	1.6
MOISTURE	9.1

Calorific Value—303 calories per 100 grammes or 1,376 calories per lb.

Further particulars and clinical trial sample will be sent on request.

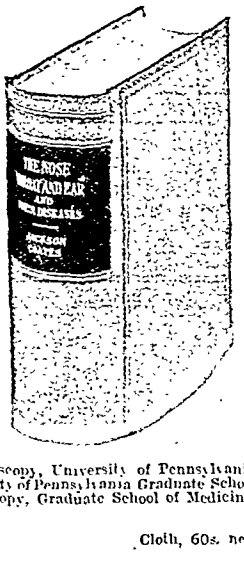
The Issue of the BRITISH MEDICAL JOURNAL is this week 39,000 copies.

Jackson and Coates on Nose, Throat & Ear

Never before has so distinguished a group of authorities been brought together to present, in one volume, the Nose, Throat, and Ear, and their diseases. Seventy-four American and European authorities have written this work, under the editorial supervision of Drs. Chevalier Jackson and George M. Coates. These authors and editors have planned this work as a book of *what to do and how to do it.* Signs, symptoms, and all diagnostic tests are given in detail. Treatment is presented from every angle—medical, including prescriptions and exact dosage; indications for surgical intervention, the actual surgical technique; and after-treatment. There are 657 illustrations and 27 inserts in colours.



"It would be impossible to appraise the merits of all the articles, so varied and so diverse, but as they must be taken collectively, it may be said that on the whole they maintain a high level and give a faithful picture of the best modern practice, with copious illustrations and admirable coloured plates."—BRITISH MEDICAL JOURNAL.

"Each section is written by one who has interested himself specially in the subject discussed, and the whole is edited by men of such eminence in laryngology and otology that its appearance is an event of some importance . . . . . The book is well produced, and the editors are to be congratulated on the general plan adopted. Most of the illustrations are excellent, a bibliography concludes each section, and, most important in a work of this scope, the index is full and adequate."—THE LANCET.

Edited by CHEVALIER JACKSON, M.D., Sc.D., LL.D., F.A.C.S., Professor of Bronchoscopy and Esophagoscopy, University of Pennsylvania and Jefferson Medical College; and GEORGE M. COATES, M.D., A.B., F.A.C.S., Professor of Otology, University of Pennsylvania Graduate School of Medicine. Assisted by CHEVALIER L. JACKSON, A.B., M.D., Assistant in Bronchoscopy and Esophagoscopy, Graduate School of Medicine, University of Pennsylvania.

Octavo of 1,177 pages, with 657 illustrations and 27 inserts in colours. Cloth, 60s. net.

Christopher's Minor Surgery

NEW

"Christopher." is something entirely new in the field of books on Minor Surgery, confining itself strictly to the subject, presenting more detailed technique, and offering a far greater number of illustrations that really visualize the technique described in the text. It can be said with confidence that "Christopher" is the newest, most complete, best illustrated, and most thoroughly practical and usable book on minor surgery in the language.

Octavo of 694 pages, with 565 illustrations. By FREDERICK CHRISTOPHER, M.D., F.A.C.S., Associate in Surgery at Northwestern University Medical School. With a Foreword by ALLEN B. KANAVEL, M.D., F.A.C.S., Professor of Surgery, Northwestern University Medical School. Cloth, 36s. net.

Wechsler's The Neuroses

NEW

This new book on the neuroses marked a real departure in the literature on this subject. Its most distinguishing feature is the strictly clinical picture of the conditions commonly classified as neuroses. Diagnosis and management of these conditions have received particular attention, and the case histories cited have been included because they have a definite relation to the phase of the subject under consideration. The book will be welcomed for the sanity of its presentation, its understanding of the needs of the practising physician, and the strictly clinical approach to the subject.

Octavo of 530 pages. By ISRAEL S. WECHSLER, M.D., Associate Professor of Clinical Neurology, Columbia University, etc. Cloth, 18s. net.

For your Patients

the Hanovia *Home Model* ("Homesun")

A safe, convenient apparatus for producing tonic effects.

THE HANOVIA HOME MODEL "HOMESUN" £12—£15.

SPECIAL NOTE.
The Home Model cannot replace the Stand Models of Hanovia Lamps used for clinical work.
In medical practice, the Home Model can be recommended as a portable lamp and for bedside use only.

The natural result of the widespread publicity given to light therapy has been the large demand from the public for a home model ultra-violet ray lamp.

Within the past few years a wide variety of so-called "health lamps" have appeared on the market. The claims made for some of these lamps, and some of the lamps themselves, have aroused the active criticism of members of the profession.

Having pioneered the development of apparatus for ultra-violet therapy, the British Hanovia Company was interested in bringing out a lamp which could be used safely and effectively by the layman.

The Portable "HOMESUN" Quartz Lamp is the result. Smaller than the lamp sold to physicians for scientific and clinical use, its rays are not nearly so intense. It is intended for *tonic* sunbaths—is offered for this purpose alone—and advertised with suitable warning against self-diagnosis and self-treatment. The importance of consulting a physician in cases of illness, the unwisdom of self-treatment, are emphasised in every Hanovia message to the public.

Every member of the medical profession can recommend with complete confidence this lamp to patients who need tonic light baths.

THE POSTAL ACCOUNT

It is often supposed that to live a long way from the nearest branch of a bank, or to be constantly unable to go to the bank in person, is a handicap to the enjoyment of the full advantages which, it is admitted, a banking account offers. Perhaps it is assumed that to conduct an account by post involves 'more letter writing', or is costly, or is not welcomed by the Bank. It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method, and offers some clear suggestions.

The Secretary of the Bank will be pleased to send a copy on application

Hernia Prevention and Control

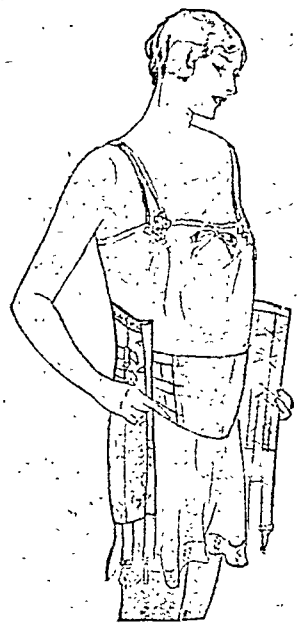
A Spencer Corset with Inner Support or A Spencer Belt is a Dependable Aid.

The Spencer Supporting Corset shown at the right combines in one garment a regular style corset and a dependable hernia support.

The garment in the illustration has been unclasped and is shewn with the front opened and held back to shew the inner supporting section which safely retains or supports the hernia.

Our Medical Department issues booklets on the uses of Spencer Supports for the relief of hernia, enteroptosis, movable kidney, sacro-iliac strain, and for maternity wear. We will gladly send you any of them in which you are interested.

A properly designed abdominal support worn after laparotomy is a reliable safeguard for those patients for whom the surgeon has reason to fear ventral hernia. After herniolaparotomy, adequate support is generally regarded as necessary.



Spencer Supporting Corset for Hernia Control.

Many surgeons prescribe Spencer Supports after all abdominal incisions as a matter of precaution.

When hernia already exists and is inoperable, a Spencer abdominal belt or corset with inner support will give comfort to the wearer, will control a reducible hernia, or safely prevent further increase in the size of a large non-reducible hernia of long standing.

Both men and women can be fitted with Spencer hernia supports. Each garment is individually designed to meet the needs of the person for whom it is prescribed.

* * *

The Spencer Corsetière will call at your surgery or at your patient's home to take measurements, all of which will be used in creating a support to meet the needs of your patient.

PHILIPS LAMPS LTD., (X-ray Dept.), PHILIPS HOUSE, 145, CHARING CROSS RD., LONDON, W.C.2

On the Absorption of Sanatogen

Why it is that Sanatogen is absorbed with ease even by the weakest stomach.

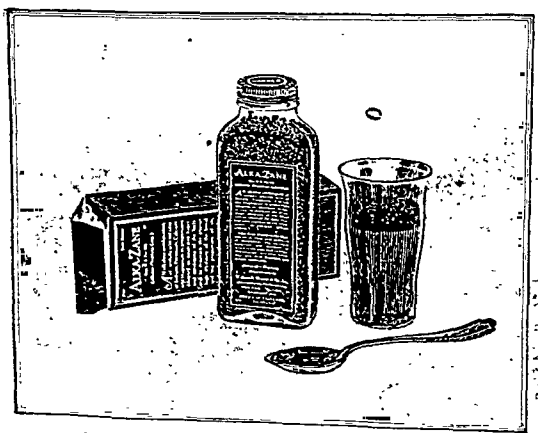
The tonic influence of the glycero-phosphoric-acid in the chemical combination casein-sodium glycerophosphate (*Sanatogen*) makes the use of casein possible in cases where the patient has to a great extent lost his capacity of absorption (Tunnicliffe, Tischer-Beddies, Chajes, a.o.).

French authorities (Robin and others) ascribe to the glycero-phosphates a great influence on the utilization of the albumin in the body. The manufacture of Sanatogen is conducted under the strictest scientific control ensuring absolute purity, sterility and uniformly high dietetic value.

Samples and Literature will gladly be sent on request to:

GENATOSAN LTD., LOUGHBOROUGH, LEICESTERSHIRE.

Immunity and Alkalinity



A pleasant, effervescent granular preparation composed of carefully-selected salts of Sodium, Potassium, Calcium and Magnesium in physiologically correct proportions.

appear, in the opinion of competent observers, to be in close relationship. At least it is certain that alkalinity is lowered in all infectious diseases, and that excess production or defective elimination of acid products lead to a number of metabolic disturbances.

To correct these conditions, present particularly in gastric and intestinal disorders, rheumatism, gout, and certain cutaneous affections, and to prevent their occurrence as a sequel to undue reduction of the buffer substances of the blood, prescribe

ALKA-ZANE

Literature and samples to physicians on request.

Francis Newbery & Sons, Ltd.,

Prepared by WILLIAM R. WARNER & CO., INC.,
Manufacturing Pharmacists Since 1856.

Therapeusis in Pulmonary Tuberculosis

By increasing the calcium content of the blood the resistance of the whole organism against the bacterial toxins is greatly strengthened, there is a decrease in the excitability of the nerves, and a definite improvement in the functions of the alimentary canal, due to the combined anti-toxic and astringent effect of the calcium salts.

Successful calcium therapy depends upon calcium retention. The calcium-sodium-lactate compound, presented as a double salt in the form of Kalzana is easily absorbed and well retained. The sodium-lactate is changed within the body to sodium-carbonate, which raises the blood alkalinity to the extent necessary to secure calcium retention.

"The Practitioner," June, 1924, says:

"It is indicated in all conditions in which a lime food is required, particularly because Kalzana promotes calcium retention."

Kalzana is in daily use at over 200 British Sanatoria and Hospitals.

Dispensed by Chemists in air-tight packets containing 50 and 100 tablets.

STIMULATES THE APPETITE AND PROCESSES OF METABOLISM

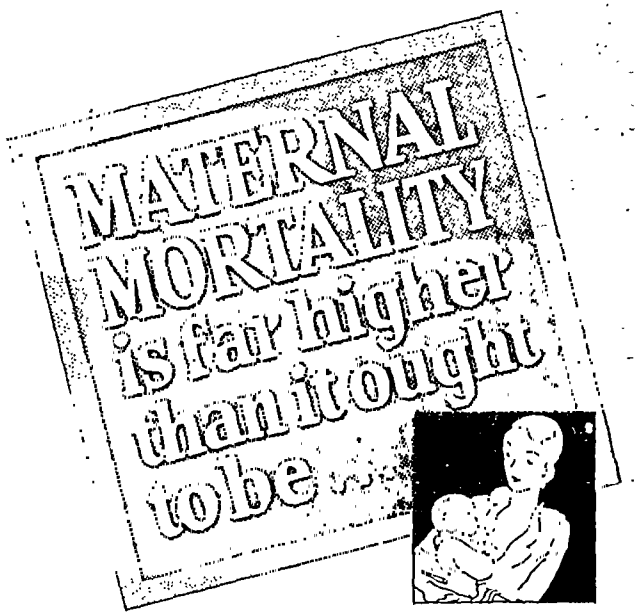
For its beneficial effect on the appetite and the processes of metabolism, and for its richness in Vitamin B, Marmite can be usefully prescribed for convalescents and patients whose strength requires building up.

Marmite is also valuable in correcting any tendency to incomplete elimination or other digestive weaknesses, particularly when such cases have become chronic.

Medical Practitioners are invited to write for a sample of Marmite, together with full evidence of its usefulness. The Marmite Food Extract Co., Ltd., 59, Eastcheap, London, E.C.3.

MARMITE

Being a Yeast Extract, Marmite supplies any deficiency of Vitamin B in the ordinary diet. It is easily administered in soups and other invalid dishes, in sandwiches, or as a consommé made with hot water.



THERE is one care: one protection against infection and disease that every mother and child should have. That is the protection of Marshall's Lysol—the antiseptic that is safe and sure for every case.

Marshall's Lysol is the only Lysol made from the original formula. A doctor who recommends Marshall's Lysol KNOWS that his patients will obtain a Lysol of unvarying strength and quality. That this is vitally important we need not stress. Every doctor and nurse knows that in midwifery, surgery, or cases of infectious disease, the highest grade antiseptic is absolutely essential.

MARSHALL'S *Lysol*

OVALTINE

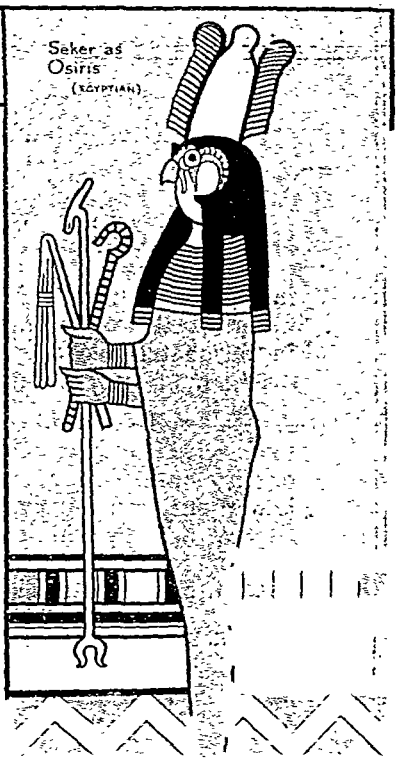
AN EFFICIENT GALACTAGOGUE.

In addition to its value as a means of promoting the nutritional welfare of the mother and child, clinical experience extending over many years has conclusively shown that "Ovaltine" has specific galactagogue properties. As a result of its administration, there almost invariably follows a marked improvement in the flow and quality of the milk.

The following is an example of many reports received:

"In more than one case I have found 'Ovaltine' bring back the milk supply after everything else had been tried. In one case I discontinued the use of 'Ovaltine' after the desired result had been obtained, but I found at the same time the milk supply also diminished, necessitating the resumption of the use of 'Ovaltine.'"

To ensure adequacy of the [illegible] order the use of "Ovaltine" to c[illegible] month of gestation and to be continued throughout the nursing period. In this way the mother is not only enabled to withstand the extra strain which the childbirth throws upon the system, but to nurse her child from the outset in the best possible way. "Ovaltine" is delicious as well as highly nutritious, and involves no troublesome preparation.



A liberal supply for clinical treatment sent free on request.

A diet of Mellin's Food

in conjunction with fresh cow's milk and water, produces an immediate gain in weight in fermentative dyspepsia and in the wasting disorders of early infancy.

As is well known, sugars exhibit varying tendencies to fermentation in the digestive organs—milk sugar ferments most rapidly, less rapidly cane sugar, and maltose still more slowly, and the high percentage of malto-dextrin in Mellin's Food accounts for its usefulness in all such cases of malnutrition.

TO MEMBERS OF THE MEDICAL PROFESSION.

BOOTS PRODUCTS

VITAMALT

RICH IN ESSENTIAL VITAMINS A, B, C & D.

It is of supreme importance that Infective processes be checked, and that the necessary supply of anti-infective agent be present in the diet. Normally, this has to be supplied as an extra-dietary measure and for this purpose Vitamalt is commended to the notice of the medical profession.

Vitamalt contains Vitamin A—well known as a potent anti-infective agent—in the proportion recommended by the leading authorities. In addition it contains Vitamins B, C, D in such proportion as renders it a valuable treatment for deficiency disorders.

It is being prescribed by an ever-increasing number of the medical profession, and the results of clinical trials enable us to state that it fully justifies the confidence which has been placed in it.

Price 1/9 and 3/- per jar.

Full size trial sample free to Members of the Medical Profession on application by postcard.

KOLYNOS
DENTAL CREAM

(Made in England)

The properties desirable in a dentifrice have been specified as follows, viz.:

Antiseptic.	Harmless to Mucous Membrane.
Pleasant Flavour.	Non-poisonous to the user.
Mildly Alkaline.	Must not alter reaction of the Saliva.
Contains Chalk as an Abrasive.	Must not destroy Salivary ferments.
Contains Soap as an Emulsifier.	Must not inhibit the secretion of the Saliva.

Twenty years of varied and painstaking laboratory experiments with the wide and ever-increasing endorsement of the profession have demonstrated that these qualities are embodied in Kolynos Dental Cream.

Write TO-DAY for free professional samples, literature, etc.

KOLYNOS INCORPORATED

CHENIES STREET, LONDON, W.C.1

KOLYNOS DENTURE POWDER

An entirely new preparation for effectively cleaning artificial teeth. Can be used on the most delicate dental plate with complete safety and satisfaction.

Antiseptic. *Convenient in use.*

EXTRACTUM GASTRICUM

An aqueous-acid-glycerin extract of the entire mucosa of the fresh stomach, including the pyloric.

Containing the peptic enzymes—proteolytic and milk curdling, the activated principles and naturally associated soluble organic and inorganic constituents. It is a stable, potent fluid, free from alcohol and free from sugar, with an acidity approximately of 0.25% absolute hydrochloric acid, loosely bound to protein, and 25% pure glycerin.

The usual dose is one to two teaspoonfuls, diluted with a little cold water.

Extractum Gastricum is put up in 6-ounce unlettered bottles without literature.

In the treatment of

Influenza

S. U. P. 36

The value of injections of S.U.P. 36 on two successive days in the early stages of influenza, and of other acute inflammatory conditions in which there is accompanying rise in temperature, was established some five years ago, and it is now well recognised in general practice.

A recent article (*B.M.J.*, Oct. 12th, 1929, p 663) containing reports of forty-two cases of influenza treated with S U.P. 36 furnishes comfirmatory clinical evidence on the subject. This evidence demonstrates the remarkable power possessed by S U.P. 36 to shorten the duration of disease by reducing the period of pyrexia, headache, and muscular pain, the findings being summarised in the following table:

Literature on request

	Control Cases	Cases treated with S.U.P. 36
Average duration of pyrexia in days ...	2.8	1.4
Average duration of headache in days ...	2.1	1.0
Average duration of muscular pain in days	3.4	1.3
Average number of days in bed	5.7	2.8
Average number of days off work ...	16.0	6.9

It will be observed that the net result of S U.P. 36 treatment is to reduce by one-half the duration of the disease itself and of its usual associated symptoms.

Local Anæsthesia in Surgical Practice

REDUCTION OF FRACTURE.

Typical Case.

B. J. J., aged 49 years.

Diagnosis: Fracture of both bones of right leg at the mid-point.

Operation: Reduction of fracture, closed method.

Anæsthesia: Sciatic nerve block.

History: Man fractured his leg in a fall a few hours previously.

Technique of Anæsthesia: The sciatic nerve was blocked at the gluteal fold, the needle point causing paraesthesia along the course of the nerve. Fifteen c.c. of a 2 per cent. Novocain-Adrenaline solution were slowly injected, and anæsthesia was complete in ten minutes. The fractured fragments, which overlapped each other considerably, were replaced by extension and manipulation. There was excellent relaxation, and reduction was made without pain, after which a plaster-of-Paris cast was applied. —Extract from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

GLANOID

CORPUS LUTEUM

DESICCATED SUBSTANCE

The Inhibitor of Ovarian Activity.

Made **SOLELY** from Pregnant Sow Ovaries.

THE value of Corpus Luteum as a therapeutic agent has been widely discussed and many physicians report favourable results, particularly for the relief of symptoms following natural or artificial menopause. Corpus Luteum medication, at the onset of the menstrual period, will hasten the flow, prevent dysmenorrhea, menorrhagia, and metrorrhagia.

As there is no method for standardising the drug for medical purposes, the importance of having reliable preparations is obvious. In the manufacture of Corpus Luteum in the Armour laboratory, only glands from healthy animals are used. The ovary containing the Corpus Luteum is removed while still retaining the animal heat and the Corpus Luteum dissected out. It is then freed from connective and other extraneous tissue, finely minced and dried in vacuo at low temperature. This is done to prevent the coagulation of soluble proteins, to minimise the oxidation of phosphatids, etc., and thus ensure the maximum therapeutic activity of the product.

"SMILER"

A MILK FALLACY.

The inadequacy of cow's milk as a food for the infant is now accepted as a general statement of fact. Intended as it was by Nature to suit the digestive tract of the calf, it is not to be wondered at that its application to the feeding of the human infant leads in so many cases to unsatisfactory results. Modern research has definitely shown that its high buffer value, its cheesy indigestible curd, its varying composition, all render it unsuited to the digestive apparatus of the young child.

Apart from this, raw cow's milk, although in itself a most valuable food, has rightly received the almost unanimous condemnation of the Medical Profession in as far as its use for infants is concerned, owing to the grave risk of contamination with pathogenic organisms either at its source or during handling.

Cow & Gate Milk Food

"Cow's Milk made safe and suitable for Baby."

Science has, however, come to the aid of practice in the shape of the Cow & Gate Improved Roller Process of drying, embodying every care and control known to-day, by which, without the loss of a single essential quality, a transformation is effected which annuls the dangers and deficiencies of raw cow's milk, and produces a milk which tests and experience of over a quarter of a century have proved to be the only safe and reliable milk food for the artificial feeding of Infants.

The makers will gladly supply samples for Clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

GUILDFORD.

Petroleum

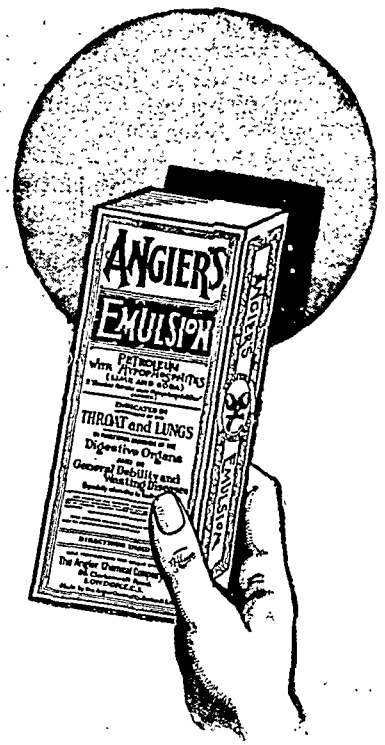
in the treatment of

Intestinal Disorders

&

Purified Petroleum in one form or another is becoming more and more widely employed in the treatment of intestinal disorders associated with toxæmia To obtain the best results, the petroleum should be not only non-irritating and free from all impurities, but it should preferably be in the form of an emulsion. In this form, the minutely divided petroleum globules mingle freely with the intestinal contents, and are more widely and evenly distributed throughout the entire intestinal tract. Maximum lubrication is thus assured and the characteristic action of the oil obtained with greater uniformity.

Angier's Emulsion is made with a specially purified petroleum of just the right degree of viscosity. It is a perfect Emulsion of cream-like appearance and consistency, and mixes instantly with water and other liquids. Pleasant to the palate and remarkably well borne by sensitive stomachs, it can be administered either undiluted or in any suitable vehicle. It has been found that patients who cannot tolerate clear petroleum are able to take Angier's Emulsion without the slightest difficulty, and continue indefinitely without ever developing an antipathy to it. Angier's Emulsion will also be found most useful as a vehicle for the administration of intestinal antiseptics or astringents, for which purpose it is eminently suitable.



"After long experience of many forms of paraffin and petroleum, both in the character of emulsions and otherwise, I have found none so satisfactory to the patient as Angier's Petroleum Emulsion."

ORIGIN OF THE ORIENTAL INFLUENCE UPON BYZANTINE AND CHRISTIAN ART.—The study of textile-finds in Egyptian graves of late Hellenistic period led investigators, at the beginning of the present century, to look to the Far East, for the origin of certain features in their decorative motifs. There were, however, no links by which such a connection could be established. Recent discoveries of decorated textiles (such as here reproduced), excavated upon the central Asian high-road over which all overland trade passed between China and the West, take us back to the time when the Chinese designers and weavers first prepared their products for export. These discoveries provide the tangible links required with "Sassanian," Byzantine and Coptic designs and thus seem to prove their Chinese origin. The principal motifs of the early Chinese decorators were "rolling clouds, scrolls and virile beasts." If the latter are bizarre in conception and incorrect as to details, they are, nevertheless, full of life and originality. A comparison of these vigorous designs with the over-conventionalised and lifeless patterns of "Sassanian" and Coptic silks suggests at once that the former represent the pioneer work and the latter the imitations. The Chinese designers used beautiful and rich colours to enhance the charm of their work.

DIPHTHERIA CARRIERS

The following extract from a recent report on the use of Dimol Snuff in the treatment of diphtheria carriers should appeal to every practising physician and especially to Medical Officers responsible for the safeguarding of the health of children.

"We are getting very excellent results with Dimol Snuff in the treatment of diphtheria carriers (12 weeks positive cultures) and 'pre-carriers' (6 weeks positive cultures)—the latter, of course, with the idea of preventing them reaching the carrier stage.

"Taking both classes together, we consider that we have been successful in about 90 per cent. or more cases.

"Most of the failures we find due to some definite chronic nasal disease.

"As a routine we use Dimol Snuff twice a day with an insufflator. If a failure occurs and it is apparently the nose itself and not a question of adenoids, then we increase the treatment to six times a day. The children do not appear to suffer any harm from the powder even in these extreme doses.

"The treatment is continued until the child has had negative swabs twice a week for 3 weeks and then another 3 weeks without snuff.

"One more point which is established is that dirty noses are all cleared up, with one exception; in this case I suspect an antrum and shall examine him for such as he is a big boy."

——— F.R.C.S.

Children can be taught to take the snuff easily and efficiently in small pinches or from the back of the hand, and soon learn actually to enjoy the mild warmth induced in their nostrils.

Observations
ON
BORDERLINE PROBLEMS IN CHILDHOOD.

BY
A. DINGWALL FORDYCE, M.D.,
F.R.C.P.Ed.,
HONORARY PHYSICIAN, ROYAL LIVERPOOL CHILDREN'S HOSPITAL.

If we recognize varying planes of sound health, life on one of the lower planes does not signify abnormality. We meet with many children in average health and we may call them normal; gross forms of abnormality—for example, inflammation, infection, deformity, idiocy—are readily detectable. But there is a wide undefined ground between normality and abnormality where answers have to be found to three difficult questions: Is the child well? What is wrong? What should be done?

These children on the borderline of the normal or healthy and of the subnormal or sick come before us for an enormous variety of reasons, with countless indefinite symptoms common to many forms of subnormality, or with suggestions and impressions that the child is not what he or she ought to be. Their study taxes the resources of medical knowledge, their care is often largely a matter of opportunity for adequate supervision, and sometimes expediency is permitted a place in therapeusis.

I seek here to dwell on some outstanding practical points, considering first the physical, and secondly the mental, aspect.

A.—Physical.

The essential error—if there is one—in a borderline case may be a local defect or disorder, with consequent disturbed general metabolism, or may be a primary general peculiarity, defect, or disorder, and treatment necessarily involves consideration of the fundamental bases of medicine. Such consideration is demanded in all cases, but with varying peaks of intensity according to the condition, and a grouping of cases into types according to complaint facilitates discussion of the general subject.

We not infrequently see children with the complaint that they are "too fat" or "too thin" or "under-size." If we agree that the complaint is justified and find no indication of a definite cause, what is to be the explanation of the condition and what the treatment? In all cases of poor nutrition and backward growth we seek first an infective cause, but failing in such search, and in the absence of the common symptoms of toxaemia, such as lassitude, pallor, etc., I think we may answer: hygiene, including diet and endocrines.

For therapeusis in this connexion endocrine practically means thyroid extract, an aid so powerful as to demand cautious usage. The important contraindications to thyroid therapy are well known, but apart from these the two main dangers in its administration are, I think, first, that it be not sufficiently pushed in cases obviously demanding it—for example, cretins—and which prove resistant to doses ordinarily accepted as moderate; and secondly, that it be used in a wide variety of indeterminate cases, in some of which it causes improvement, but by its action hides the fundamental difficulty or error—for example, dietetic or digestive. Thus intermittent mild glycosuria is not necessarily a contraindication, particularly when associated with a high fatty diet, but improvement under thyroid therapy may obscure recognition of the basal trouble. In the case of a borderline child there is often a degree of thyroid instability, and while minute doses of thyroid extract may help to stabilize thyroid activity, yet the cause of the instability has still to be sought.

If environment, diet, and general hygiene can be controlled success should be obtained, but just these conditions are so often the unobtainable desiderata. Lacking satisfactory control in such directions, small doses of thyroid are often beneficial, and perhaps particularly so in the case of girls about the period of the commencement of puberty. But thyroid should not be given for the solitary symptom of fatness—obesity—and it should never be given to a child simply to make the child thinner.

Vitamin administration may also be considered in these cases—particularly those of "under-size" or "too thin." In cases of definite illness—rickets, for example—an indication exists for the administration of a definite vitamin, and such administration can be effectively carried out by special diet, or by synthetic drug preparation, or by artificial sunshine, or by all combined. In such a case the treatment must be pushed. In the borderline children there will be no special call for any definite vitamin, and satisfactory provision for vitamins should be present under ordinary hygienic conditions. But for these same borderline children exposure to artificial sunshine is often of distinct benefit, provided exposure is short and mild, and it is sometimes most useful when associated with small doses of thyroid and of ephedrine. Such treatment is perhaps particularly useful in the cases of sallow or pigmented children.

Another large group of borderline children is that in which the symptoms complained of are many and varied, but grouped in all cases round the central complaint that the child seems languid, weak, pale, easily tired—and *without definite cause. Such a combination of symptoms* can be coalesced into the diagnosis "debility," and this possibly disintegrated into the further definitions of pre-tuberculous, or pre-rheumatic, or hypotonic, or catarrhal, or intestinal, or nervous. The child I have in view at the moment has no marked catarrhal, intestinal, or nervous symptoms, and might be placed in one or other of the first three groups—if such groups be recognized. These terms, however, are not those of diagnosis, but rather the pious expressions of a groping for diagnosis.

In these cases we consider family and personal history, and from them we may receive guidance to diagnosis and treatment—or we may not. If on full examination there is no discoverable abnormality in the child, it is right that we should concede to our clinical training its due and, accepting negative clinical signs, attempt to glean information from the facts of environment and habits of daily life. Is the mental and material environment healthy? Is school work suitable? Is the sex position normal? With all our trying we may fail to define a cause, and if treatment appears advisable we should base it on the fundamental principles of therapeutics—rest, fresh air, simple diet. The greatest of these is rest. The healthy child is never lazy—he bubbles over with physical and mental activity. A child does not like to be guided into lines of activity, or, rather, may be guided into lines to which he objects. Thus he may get easily tired if forced to continued monotonous physical exercise, or he may appear lazy if asked to do school work above him or below him. *His bodily* and mental processes are active but spasmodic, and if guided indiscreetly easily tired. If the child of whom we speak is languid and wishes to stay in bed he is abnormal, and should be kept in bed till he asks to get up. If any reasonable cause for change in mental activity can be found it should be fully explored.

It is important that the child should not be exploited in the light of the value of fresh air. Desperate illnesses demand desperate remedies, and even our climate often helps to cure desperate illness. But this child requires as much fresh air as can be sensibly obtained by educated guardians in view of the climatic conditions prevailing.

In relation to consideration of diet there is just one point to mention at present. For most children of the type of which I speak iron is bad treatment, and pallor and languidness are often secondary to gastro-intestinal disturbance. But for apparently causeless mild anaemia in young children with no digestive abnormality the administration of a few grains of iron daily often has most rapid and excellent results.

There is another group of cases in which the complaints relate to excessive or diminished appetite, vague symptoms of indigestion, irregularity of bowel action, and biliousness. Most parents to-day have a considerable if superficial acquaintance with the details of dietetics, and seriously endeavour to feed their children correctly. They

further pride themselves on not being faddy, but open to modern teaching. Among the well-to-do, however, two slogans are often obeyed to excess—the call for vitamins and the restriction of meat. All parents like to see their children big and strong, and it comforts their hearts to know that butter, eggs, and cream, as well as vegetables and fruits, are rich sources of vitamins. At the same time they read of the dangers of excessive meat in the diet, and the wisdom of curtailing this article in the dietary of the child. As a result the diet of very many children contains too much fat and too little meat, and in countering these tendencies lies much of medical work in borderline children. Acidosis is a popular term and a common subterfuge for a diagnosis. But a real tendency to the condition is, of course, also common, and accounts for the value of alkalis as tonics for children. There is also a further reason for the value of alkalis and big doses of alkali, which I believe is more common than is sometimes suspected. This reason is the condition of coli-uria or coli-pyuria in girls, and chiefly young girls. In babies the condition is usually so acute as to pass beyond any borderline stage, but in a less acute form it is common in young girls as a cause of borderline symptoms without hint of urinary origin.

The diagnosis of "latent tuberculosis" in the complete absence of signs on thorough examination, though possibly often a correct diagnosis in view of the very great incidence of infection, must yet be frequently no sufficient explanation of symptoms or condition present. Latent tuberculosis must be arrested local infection, and such infection is *compatible with general fair health—with* adequate growth and nutrition. Indefinite symptoms may be caused by toxaemia from the tuberculous focus, or may be due to some quite different intercurrent condition. All the more important is it that because the child is considered tuberculous other abnormalities should be sought for and treated.

In the case of some children the main complaint is frequent colds or sore throats—recurrent nasopharyngeal catarrh and infection. An occasional cold is part of the physical education of youth, but frequently repeated colds overstrain resisting processes and may produce a local focus of weakness and possibly, further, of infection. The dividing line between education and danger is hard to define. Who dare be so bold as to dogmatize? Having considered the general aspect in each particular case, there remains the question of local interference. Have the tonsils and adenoids become a source of weakness and danger, and should they be removed? This we may say: in borderline cases it is wise to postpone tonsillectomy if possible until the child is at least 5 years of age; and, further, when the operation is performed we should see that it is a true tonsillectomy and not merely a tonsillotomy. It is possible that there may be occasions when tonsillotomy is indicated, but tonsillotomy performed when tonsillectomy is indicated is bad medicine and probably also bad surgery.

Particularly during recent years great emphasis has been laid upon the symptoms of nervous instability in children. We rarely see a child who is not described as nervous. Nervousness is a complaint. But all children must always have been nervous if by the word we are to understand instability and ready excitability of the nervous system. It is possible that the nervous system of many children during the past fifteen years has been more excitable than in previous generations, but it is certain that the nervous phenomena of childhood have been more closely studied by a nervous public than has been the case for a long time.

The complaint with our borderline children is nervousness, possibly abnormalities of sleep and enuresis, pains, twitchings, and occasionally stammer. If a child has chorea, habit-spasm, or a definite stammer, he ceases to be borderline. Are the symptoms present because of innate physical make-up or because of influence from without, material or mental? It is impossible for anyone to alter the peculiarities of heredity—the child is the offspring of his parents—but it may be possible to counteract special tendencies if they can be determined, and for the rest we must seek for and deal with material and mental influences. *Thus we* must see that the *condition* is not one of primary physical unrest or disorder in which we may, for example, by giving alkalis, by releasing foreskin, or by removing worms, directly cause improvement. Very often in order to reach the child we have to work through the parents, and in all cases we need their hearty co-operation.

Among important possible causes which should be sought for are slight and unsuspected abnormalities of sight or hearing which may give rise to trouble in school.

The last two types of children I shall note under the heading of physical defect are those where, in the first place, the complaint is that the child is dull, stupid, placid, and quiet; and secondly, where the child is described as naughty, unreliable, and irresponsible. The first type of complaint to a doctor is rare without distinct physical or mental abnormality to account for it, if we except the group of borderline mental cases in whom the dullness is usually brought into prominence through scholastic efforts.

With regard to the latter type, it is merely necessary here to note that such a master of the subject of nervous conditions in childhood as the late *John Thomson wrote* of "abnormal naughtiness in normal children"; it is advisable, therefore, to be cautious in labelling a child as a post-encephalitic.

B.—MENTAL.

Consideration of the last two types carries our attention to *borderline children in whom mental traits or characteristics* or symptoms are the chief cause of anxiety to parent, schoolmaster, or doctor. Is the child mentally normal? In attempting to answer this question we must proceed carefully along a path which, though tortuous, differs in no fundamental respect from that we customarily travel in purely physical cases.

Thus here we deal with a central factor—the independent capability of the child; and two environmental factors—the home and the school; and we have to consider the nature of each of these environments, their influences on the child, and his reaction to them.

Our examination, then, can be considered under three headings:

(*a*) Ordinary medical physical examination, including facts of history and environment.

(*b*) Investigation into temperamental and social conditions and reactions.

(*c*) Scholastic reports and tests of general and scholastic intelligence.

Ordinary medical examination and investigation conducted in the usual manner must form the essential basis for a considered opinion. Thus it is important to commence with inquiry into details of family history. While gross mental defect is usually a sporadic occurrence it is very striking how borderline children tend to be born of a borderline group of the community—are of borderline ancestry. Also striking is the tendency to large families and high mortality. Further, facts of illegitimacy, mixed breed, extreme poverty with large family, alcoholism, and criminality in themselves favour suspicion. The influence of syphilis is, of course, hard to assess, and its direct effects appear to be either very striking or *little* marked.

As regards personal history, very important points are the nature of the labour and the condition of the baby at birth. If the baby was definitely a "blue baby," if he *appeared moribund; or if he took fits within the first few* weeks of life—particularly within the first few days—all such histories strongly favour a diagnosis of mental defect.

Any discoverable physical defect has an important bearing on the mental position. A child growing up with a severe physical defect tends to have an unusual mental outlook, but though many are very backward from lack of opportunities of varied experience or schooling, yet they *may be otherwise distinctly clever. Also the nature of the* physical defect is obviously of very great importance, as it may in itself directly affect mentality—for example, spastic diplegia resulting from birth trauma.

When dealing with children who show no gross or obvious defect, physical or mental, examination is concerned with search for inconspicuous abnormalities—*defects which*, though inconspicuous, may yet have important bearings on the mental status. Thus it is important to decide if there is any suspicion of chronic toxaemia—intestinal, tuberculous, or rheumatic. Is there

any reason to suspect such a latent constitutional condition as may conduce to nervous and mental symptoms—for example, backwardness at school work, dullness, variability? Is the nasopharynx healthy and free from infection, or is there a history of recurrent catarrh, enlarged cervical glands, or otitis? Are the eyesight and hearing normal, or so nearly so as to cause no possible trouble with school work in a large room? Very minor degrees of abnormality may yet cause trouble in a big class, and a child reprimanded for apparent inattention, naughtiness, or impudence may be driven to apparently abnormal and peculiar reactions.

Are the deep reflexes normal? It is not uncommon to see cases of birth trauma which have been so inconspicuous in their physical effects as even to escape treatment by the orthopaedist, or which have been treated by him for minor local deformities. A clear epileptic is, of course, outside the borderline group, whether the epilepsy be idiopathic or secondary to birth trauma, primary amentia, or infantile cerebral paralysis. But occasional fits spread over years and brought on by acute circumstances, and the rare occurrence of pyknolepsy, sometimes leave the matter of mentality so far open. A definite history of encephalitis lethargica likewise places a child beyond my present scope, but in conduct cases an indefinite history may clinch a diagnosis made on the appearance, manner, and behaviour of the child.

After a thorough examination, then, some defects may have been found, but there may still be uncertainty regarding mentality, and it remains to decide if the symptoms or conditions complained of in the individual child are within the bounds of the normal. There is no sharp dividing line between the normal and the feeble-minded, or, as it is stated in the recent report of the Mental Deficiency Committee (*p. 92*), "*the defective merge* into the normal by insensible gradations."

There can at present be no accurate scientific line of division between the two classes. In the ordinary *private practice of our profession we require unequivocal* evidence of mental subnormality before giving an opinion that a child is mentally defective—feeble-minded. This medical standard, which certainly exhibits reluctance to signalize or stigmatize as defective, may be regarded as giving the benefit of the doubt to the child, excluding from definition as abnormal borderline children, lowering the boundary of the normal. With the advance of research and knowledge in *psychological medicine*, with the recognition of claims for specialized education, and with national acceptance of responsibility for the care of irresponsible persons, attempts have been made to define with greater accuracy the *borderline between normality* and defect, and statutory definitions have been formulated by the Board of Education and the Board of Control.

In the Elementary Education (Defective and Epileptic *Children*) Act, 1899, defective children were defined as children who "not being imbecile and not merely dull and backward, are by reason of mental or physical defect incapable of receiving proper benefit from the instruction in the ordinary public elementary schools, but are not incapable, by reason of such defect, of receiving benefit from instruction in such special classes or schools as are in this Act mentioned." This *section* was *included* in the Education Act, 1921, and stands to-day.

The Mental Deficiency Act, 1927, defined four categories of mental defectives—idiots (the lowest grade), imbeciles, feeble-minded persons, and moral defectives—and the definition of feeble-minded persons is as follows:

> "Persons in whose case there exists mental defectiveness which, though not amounting to imbecility, is yet so pronounced that they require care, supervision, and control for their own protection or for the protection of others, or, in the case of children, that they appear to be permanently incapable by reason of such defectiveness of receiving proper benefit from the instruction in ordinary schools. . . .
>
> "For the purposes of this section 'mental defectiveness' means a condition of arrested or incomplete development of mind existing before the age of 18 years, whether arising from inherent causes or induced by disease or injury."

It will be noted that in the definitions regarding children, whether by the Board of Education or the Board of Control, the predominant note in the test of the child is benefit from school—scholastic progress. This appears to exalt to pre-eminence a secondary though important element in diagnosis. The suggestion has now been put forward in the report of the Mental Deficiency Committee that "the only really satisfactory criterion of mental deficiency is the social one." If this be adopted it should bring the statutory definition closely in line with the definition in general medical practice, while, with newer methods available, doctors are in a position to define with greater precision.

Having, then, made a thorough physical examination of the borderline mental child it is necessary to investigate his temperamental and social characteristics, these being dependent upon his emotionality and general intelligence.

Stigmata can be very misleading, but the manner and appearance of a child at ease and under examination often give valuable information. There is to be noted, perhaps, a shambling or furtive gait and manner, or the child may be exceptionally facile, smiling, docile. He may exhibit a noticeable lack of shyness, or have a superficial vivacity without fixity of idea or purpose; or, on the other hand, with a superficially bright appearance, be irresponsive and reticent, have blank eyes, and be inane and meaningless in manner.

From home history is to be discovered if he exhibits in ordinary degree the common home virtues and vices, or in what way he manifests peculiarity. It is often hard to judge from this history, and too much reliance cannot be placed on isolated statements. If striking they arouse *suspicion, but insight into the environment is as necessary* as into the child's temperamental manifestations. He should, of course, disclose signs of ordinary home affections—should not, for example, be wantonly cruel to the baby, *and should not be notoriously spiteful and destructive* or aggressive. He should not be too naughty and uncontrollable, but equally he should not be too good. As Stanley Hall writes of a boy approaching the teens; "Morally he should have been through many if not most forms of what parents and teachers commonly call-'badness,' and Professor Yoder even calls 'meanness.'"

Peculiar habits are, of course, noteworthy and suspicious—such, for example, as pica, indiscriminate spitting, cutting or biting, sticking pins into people, etc. On enuresis and night terrors little importance need usually be laid, but "wanderings" away from home require careful investigation and are an important symptom.

What initiative is shown in scholarly or hand work, in the laboratory or workshop, in games or gangs? Can he reliably *carry out instructions, go messages*, correctly account for change? Does he adhere to a purpose and carry it out? Has he any special aptitudes? Is he to an ordinary degree amenable to discipline or punishment? *Does he co-operate with others*, or is he solitary among his fellows? This is a most important point of information, and it is a most suspicious sign if a physically healthy child is solitary at school or only plays with those who are markedly his juniors.

What information can be obtained from the child regarding home and school conditions? What is his explanation of alleged peculiarities—has he a possibly satisfying explanation? While, *regarding school work, there are many* points on which information is important no point is more important than the fact—if it is a fact—that the child is solitary at school. Such a condition means that the *child is failing in the social test*—a test of far greater importance than any merely scholastic one, any test dealing with the acquisition of knowledge of the three R's. Scholastic backwardness is no more a *proof of mental defect than it is of genius*, but in cases of mental defect scholastic backwardness is a common sign. It is important, therefore, to know the child's capacity in this direction, the class he is in, and the progress he is making. How much schooling has he missed? Is he competent in an average class for his age, or how much is he retarded? How does he do in hand work? Apart from any tests it is of first importance to learn such facts from school. The opinion of the teacher as to the mental status is most desirable, but the facts of scholarly progress are essential—the exact position attained in reading, writing, and arithmetic.

These facts having been obtained, there remains for investigation the response to tests of scholastic and general intelligence.

The Binet-Simon tests as commonly used are certainly of great assistance in defining the degree of intelligence when these tests are faithfully and intelligently carried out—otherwise they may be most misleading. The scholastic standard set in the associated tests commonly used is, on the whole, I think, high. There is no special difficulty in carrying out the tests, but the value of their results depends on strict adherence to instructions. In fact, there is a right way and a wrong way in which to carry them out, and they are worse than useless unless carried out in the right way.

As regards guidance in the care of borderline children, the doctor naturally advises about physical treatment. He must also act as guide in home and school management, and make clear to parents the methods peculiarly suitable for the child. Is there call for restraint or stimulation, exercise or rest? Is it encouragement—is it punishment? If the latter, what is the place of corporal punishment? It is common for children with an inconspicuous physical ailment or defect to be "naughty," and certainly corporal punishment is illogical and bad treatment for them. For most borderline mental children corporal punishment is likewise bad, but I cannot agree that there is no place for such treatment.

The advances of modern psychology and the probings and criticisms into so-called mechanistic physiology in relation to mental processes have introduced into the life of the child an intensified atmosphere of psychical attention which is not only common among the educated classes but is developing rapidly in the form of schemes—child guidance, mental hygiene, social welfare—for the benefit of the less well-to-do.

In the case of the wealthier brother, parent, schoolmaster, and doctor usually together decide the course of events, and it is well that the doctor guide the schoolmaster by information regarding the make-up of the child if the child requires special attention. For the poorer brother it is no less necessary that the doctor should guide the ship of health—bodily and mental—but for this child, with possibly more stormy seas to sail, there is at the same time more tendency to divided command.

The difficult child, the "maladjusted" child, the conduct case, may be a physically and mentally normal child, likewise so may be the dull and backward child. But many of all types are not. It is necessary in all cases where difficulty or doubt as to conduct or mentality arises that both the physical and mental capacity of the child be determined, and that full inquiry be made into all circumstances of the environment, material and mental. For this latter work, when done by child guidance clinics, psychologists and psychiatric social workers are essential, and team work is invaluable.

Two important points have, however, to be remembered. All children—and particularly borderline children—can have too much attention, can have their paths made too clear for their own good. Whether these children require to be dealt with by team work, or only the care of an individual, the medical man is the only suitable person to control the case.

With the diffusion of superficial medical information, however, there is a tendency for both physical and mental borderline children to be dealt with in association with very tempered medical control, and to take his rightful place in guidance the young practitioner must be fitted to aid both puericulture and pedagogy by defining indications for each borderline case. For the young graduate to carry out this work efficiently he must be fully and widely trained in the functions of normal childhood and in the beginnings of childish disease and disorder.

PAPILLOMA OF THE BLADDER.*

BY

J. B. MACALPINE, F.R.C.S.Eng.,

HONORARY SURGEON AND SURGEON IN CHARGE OF THE UROLOGICAL DEPARTMENT, SALFORD ROYAL HOSPITAL, MANCHESTER.

The name papilloma indicates a tumour made up of hypertrophied papillae, and is a generic term applied to any of the warty growths of the body. A vesical papilloma is, however, a unique tumour, having no counterpart in human pathology outside the urinary tract, and one about which the most divergent views are expressed by men of standing in urology, a fact which I will illustrate as I proceed. Two problems invite brief preliminary discussion.

1. *Do all papillomata if left to themselves eventually undergo malignant transformation?*

It is a prevailing opinion that whilst many papillomata are definitely malignant in the earlier phases all the so-called benign papillomata are to be regarded as pre-malignant tumours, and if left untreated they will in course of time undergo malignant degeneration and destroy life, a view which was first advanced by Civiale, the French urologist. Statements to this effect occur without discussion in many leading textbooks, and the assumption forms a working hypothesis to which, I think rightly, we all conform, giving an allegiance which in practice is desirable because it produces a degree of vigilance and solicitude which would not otherwise be attained, and which helps to safeguard many patients in whom recurrence does actually occur. It is a view, however, which is not by any means universally accepted. Nitze himself, on an experience of 177 of these tumours, was emphatic in his view that most papillomata are actually benign, and considered that by christening them "Zottenkrebs" (tufted cancer) Rokitansky had caused much confusion. Again, Syring in 1911, during a careful study of this subject, found astonishingly little evidence in support of the hypothesis of metaplasia. For the present the question remains an open one, but recent literature tends to support the views of those earlier writers who regarded all papillomata as definitely malignant. It is hard, however, to agree entirely with this view, for many cases are on record running for ten years or more—in my own series there are three—and cases are reported by Fenwick and Geraghty having histories extending over twenty years and ultimately ending fatally from carcinoma. The long history in such cases appears to me definitely to preclude malignancy in the earlier period, whilst, on the other hand, their termination suggests that even very benign tumours will eventually take on malignancy.

2. *How shall the nature of the growth be decided?*

The problem of differentiating a simple from a malignant papilloma, or of deciding at what stage a simple papilloma has taken on malignancy, has baffled both clinicians and pathologists. It is remarkable that after all these years the criteria of malignancy are still uncertain. There is much divergence of view in the copious literature regarding papillomata as to whether they shall be judged by their clinical or by their pathological features. At the outset I would invite your consideration of the desirability of attempting a pathological diagnosis. The uncertainty of the pathological opinion regarding these tumours is almost a byword, and different pathologists have not infrequently reported differently on the same section. It has happened in the experience of many surgeons that a tumour has been reported as malignant and its recurrence as simple; or that a tumour reported as simple has destroyed life by metastasis; or again, that of one reported malignant a clinical cure has been achieved. Further, a tumour regarded by the pathologist as simple has recurred in the suprapubic scar as a malignant growth and has destroyed life.

It is not uncommon for two papillomata to be encountered in the same bladder, of which one is apparently benign and the other malignant. Moreover, it is stated that malignancy may be observed in one part of a tumour

* Read in opening a discussion in the Section of Surgery at the Annual Meeting of the British Medical Association held in Manchester, July, 1929.

of which the remainder is apparently benign. In a viscus seen comparatively recently a large area of the base was infiltrated by a hard scirrhous mass, whilst on the lateral wall close to the exit was a villous covered tumour the size of a cherry of quite different macroscopical appearance, which on section proved to be a malignant papilloma. Such mixed growths are not very uncommon, and Fenwick[1] believed that "certain epitheliomata of the bladder are able so to irritate the surrounding healthy vesical surface that . . . benign papillomata spring up." An alternative explanation would be that a portion of a papilloma had undergone malignant degeneration which was not shared by the remainder of the growth. These features afford a convenient explanation when pathological reports and clinical course do not correspond, but emphasize the importance of serial sections of these tumours. They illustrate the occasionally peculiar behaviour of the neoplasm under discussion, and, I hope, provide some excuse when we are decoyed into error by a papilloma's idiosyncrasies.

Moreover, there is disagreement regarding whether the pathological material shall be acquired from the intravesical prominence or from the tumour's base. Each site has its advocates. Thus Buerger,[2] Beer,[3] Young and Davis,[4] and others recommend the superficies, whilst Geraghty[5] states that "the base of a papilloma may show no signs of infiltration and yet the tumour may be distinctly malignant in its body and periphery." Later he agrees that "probably in no other tumour have so many mistakes been made by pathologists." In another communication, however, the same writer[6] states that "in the vast majority of cases there was not sufficient evidence to indicate whether a tumour would respond to fulguration." Other writers (Ziegler,[7] Orth,[8] etc.) who are in favour of pathological investigation advise that the base be examined, and many indeed deny that any opinion can be formed from an examination of the intravesical prominence.

Quite apart from the question of whether microscopical examination of the tumour is worth while it must be acknowledged that there are practical objections which concern the methods of obtaining such pathological material. If it is decided to examine the superficies of the growth this will be acquired by the cystoscopic rongeur. But gentleness is fundamental in dealing with papillomata because of their great tendency to disseminate, and though the danger may to some extent be mitigated by immediate lavage with fluids intended to destroy grafts I have always held that the use of the cystoscopic rongeur violates first principles. I am disposed to think that the microscopy of the superficies of a bladder tumour is valuable, but greatly doubt the wisdom of practising it. If, on the other hand, the base is selected for microscopy it can only be obtained by open operation, and this is unfortunate, for the excision of the growth must then be completed at the time of this operation, and the uncertainty with regard to the diagnosis may lead to lack of boldness in removal.

These practical difficulties and the demonstrated uncertainty of the pathological diagnosis have led me to rely solely on clinical, which in fact, means cystoscopic, data for my diagnosis. Moreover, in my practice growths which are judged to be simple are treated by perurethral diathermy, and as the pathological material is thus destroyed, it is but rarely that the opportunity occurs for the microscopical examination of early benign papillomatous tissue. Only those cases which are submitted to open operation because they are regarded as carcinomatous supply pathological matter.

Cystoscopic Diagnosis.

"In the diagnosis of bladder tumours cystoscopy celebrates its greatest triumph," said Nitze,[9] the originator of modern cystoscopy. Written by the one who first possessed means of looking into the interior of the living bladder these words disclose an explorer's zeal on first experiencing the wonders of a new world. Since his day, through reiteration, such expressions have lost their early freshness and have even grown trite; yet I suppose that each of us has experienced some like emotion on first discovering a papilloma and realizing the scope and value of cystoscopy in the diagnosis and treatment of bladder growths. For cystoscopy is our single yet sufficient approach to a knowledge of these structures. Through it we determine the presence, the position, the shape, size, variety, and nature of the neoplasm, whether it is single or multiple, and we furthermore decide what treatment is appropriate.

Composed of clumps of dainty mobile villi, a shade darker in colour than the vesical mucosa, a benign papilloma when still small is an elegant object, whose attractive appearance would seem to preclude its eventually malign propensities. The longer and more delicate its villi the more benign the growth. The less these features are in evidence the more it is suspect. In rare instances long fragile streamers float in the bladder fluid like seaweed in a rock pool. As the papilloma grows, however, this mobility and elegancy recede, the villi becoming more stunted and swollen, their epithelium getting more granular and losing its lustre. Many growths, indeed, when quite small show this coarser exterior, and must already be regarded with misgiving. Finally, surface necrosis appears, a feature which is indicative of malignancy, though when sepsis is present, as so often happens, it requires some acumen to differentiate between ulceration and a film of muco-pus adhering to the villi.

The surface appearance of a papilloma is related to its microscopic features. The villi of a benign growth are clothed with an epithelium which in arrangement imitates the transitional epithelium of the bladder quite closely. It therefore has a colour similar to that of the bladder wall, and reflects light well. In the less benign varieties the layers are more numerous and therefore thicker, which accounts for their coarser and paler appearance. They are also less evenly arranged and stain less uniformly, whilst the epithelium of adjacent villi coalesces—a fact which is responsible, in some degree at least, for the apparent shortening and for the stunted appearance of their villi.

The appearance and characteristics of the pedicle should supply strong evidence with regard to the presence or absence of malignancy, but this evidence is more often than not denied to us because the pedicle is hidden beneath the mass of the papilloma. When the pedicle is exceptionally long it may remain uncovered. In early growths it is sometimes visible before the villi have developed, but as a rule one must judge of its development by deduction, noting whether the contour of the growth's rounded lower margin suggests a high or a low origin for its inferior branches.

After the earliest stages development chiefly concerns the main body of the tumour. The pedicle, however, gets thicker, and in due course may overtake the superstructure in breadth. I have often diagnosed a stiffening of the pedicle through employing a manœuvre which Jocelyn Swan[10] suggested. By running the high-frequency current through a diathermy electrode whilst it is in contact with the neoplasm, adhesion between the two may be obtained, whereupon gentle traction on the growth will indicate the degree of its mobility on the pedicle. A thin, flexible, and relatively long pedicle occurs with a benign papilloma; a stout, stumpy one indicates malignancy. A large villous covered growth which is completely sessile is certainly malignant.

The type which is sessile over a wide area without much projection into the bladder has a very unfavourable outlook. Moreover, if swollen mucosa or actual bullous œdema can be detected near the base it must be regarded as of evil omen. This is one of the points which should be looked for when the growth is first seen. After it has been treated endovesically there may be some inflammatory swelling at the base due to the burn, and it may be quite impossible to distinguish this from true neoplastic infiltration. Its presence or absence should therefore be remarked when the first cystoscopic examination is made. Beer[11] called attention to the danger of this mistake in 1911, within a year of the first use of diathermy. Cabot[12] called it a "pseudo-carcinoma," and states that it takes anything up to three months to subside. I have on two occasions had patients referred to me on account of such a "pseudo-carcinoma." In each instance the surgeons had reburnt the supposed growth to obtain a cure. In each, as might be expected, the lesion was aggravated, but when allowed time it subsided completely. If, after a

reasonable period of waiting, the cystoscopic appearance is still indeterminate, a portion of the bladder wall may be removed by the cystoscopic rongeur and submitted to the microscope; but there is some danger of acquiring the inflammatory part of the tumour only, as in five instances recorded by Frater[13] in which such material was reported upon as inflammatory, and in each the disease eventually proved to be malignant. Prolonged cystoscopic vigilance is probably easier and more satisfactory than any other means of investigation, as, if the lesion is due to the burn, it will recede, whereas if it represents malignant infiltration it will be progressive. The opposite mistake has also occurred, a "pseudo-carcinoma" being excised by open operation, after which its inflammatory nature was recognized by microscopy (Barney).[14]

In about one-third of all patients the papillomata are multiple. Usually not more than two or three are to be found, but occasionally I have seen them so numerous as to be uncountable, a condition which has been termed a "diffuse papillomatosis." When multiple the appearance of the secondary growths denotes a degree of malignancy in excess of that which the parent growth showed at a corresponding stage in its own development. Opinion is divided regarding the significance of multiplicity in these papillomata. Thus Swan[10] and others believe that multiplicity is no evidence of malignancy, whilst Young and Davis[4] say that they are "almost surely malignant," and Fenwick[15] says "the prognosis of cure after operation will never be so good or so hopeful in multiple as in single papillomata." Whatever the truth regarding the significance of plurality it unquestionably portends a great tendency to return, and successive recurrences are progressively more malignant. Such daughter growths are generally small and are quite easily destroyed by diathermy, a measure which is very suitable for these small splashes.

This is a thumbnail sketch of a papilloma and its malignant successor. For the former there is unanimity as to the suitability of perurethral diathermy. For the latter there is almost equal accord that, if it is operable at all, open operation must be employed. But in the transition lies the difficulty. Once malignancy has supervened, diathermy must be abandoned. All features of the growth must be reviewed before a decision is arrived at. It cannot be expected that different surgeons will express identical interpretations regarding the individual members of these borderland types. This probably accounts for the wide discrepancies in the numbers of benign papillomata and malignant ones which make up the lists of different writers. Thus Barringer,[16] out of a total of 53 growths, gives 7 papillomata, 40 carcinomas, and 6 which are of types not now being considered, whilst Egger,[17] out of a total of 80, gives 38 papillomata and 42 carcinomas. It is presumed that these surgeons draw their cases from similar sources and that the differences in percentage are explained by the different standards of the several investigators. When in doubt it may be wise to try the lesser measure of cystoscopic desiccation first, a practice which I have largely followed. A simple tumour reacts thereto much more favourably than does a malignant one, and the result of treatment is helpful in forming an opinion. Many authorities, indeed, rely so much upon this reaction of the tumour to diathermy in forming an opinion regarding its nature that it has been called the "therapeutic test."

But this method also is not without its disadvantages, for there will be delay before it gives its verdict, during which the tumour may be becoming inoperable. Furthermore, we are hazarding the dissatisfaction of our patient, who, having undergone treatment which held promise and has failed, is now advised that more radical measures are desirable. The danger of losing the confidence of a patient at the end of a series of unsuccessful treatments is a real one, and one which must be taken into account, for he may decide against further treatment, to his own disadvantage and with serious loss of prestige to his adviser. The task of at first sight placing these borderland growths in their correct categories is a difficult one, and one on which finality is by no means yet reached. In view of the improvements in the technique of partial cystectomy I feel that if diathermy is not plainly succeeding there should be no delay before adopting open operative treatment. When diathermy was first introduced it was thought that all tumours might show themselves responsive to it, but it was soon evident that whilst the benign varieties are very susceptible thereto the malignant ones do not react favourably, and may even be stimulated by it to more rapid growth. All writers are now insistent that as soon as malignancy is an established fact perurethral desiccation shall be dispensed with; but, more than that, a review of the recent literature makes abundantly clear the growing consensus of opinion that if there is a definite suspicion of malignancy superior results will be obtained in a series of cases by assuming malignancy and proceeding to resection of the whole thickness of the bladder wall.

Cystography.

Unfortunately a number of patients are not seen by the surgeon till the tumour is so advanced that even its cystoscopic recognition is difficult or impossible. The difficulty may arise because the bladder is almost or quite filled by the growth, or because, owing to cystitis or infiltration, it is small or intolerant. Haemorrhage, however, is the commonest cause, and it may be severe and intractable, or may be excited by even the gentlest of vesical washings. In any one or a combination of these circumstances cystoscopy may be so much hampered that little or no information is obtained. We may then with advantage resort to cystography. By filling the bladder with some solution which is radiographically opaque a silhouette of its cavity may be obtained on an *x*-ray plate. A tumour present in that cavity will be shown by an area of diminished opacity within the *x*-ray shadow. Though not capable of giving us the detailed information obtainable from cystoscopy this examination will nevertheless confirm the suspicion that a tumour is present, indicating its size, the site of its origin, the extent to which it projects into the vesical cavity, and as a rule will show whether its surface is villous covered or smooth. Moreover, it will indicate the shape and size of the bladder itself, and thereby it is often possible to judge the likelihood of infiltration. The bladder in epithelioma gives some quite characteristic distortions which experience makes recognizable.

I have during the last ten years seen 91 cases of papillomatous disease, with the majority of which I have been in communication recently, and, indeed, they are followed and periodically cystoscoped for two years after the bladder appears to be free from growth. It appears to me preferable, in the limited space at my disposal, to select points of interest from the series and to outline my conclusions on diagnosis and treatment, rather than attempt an analysis of these cases.

Aniline Dye Workers.

In this series there are 6 cases which have occurred in workers in aniline factories, 5 of those being from this city and 1 from elsewhere. It has been known since 1895 that those employed in aniline factories are unduly prone to suffer from this disease. Rehn, at that date, reported 3 cases in Frankfort-on-Main, and his communication aroused considerable interest in many dye manufacturing districts, particularly in Germany, where this industry was mainly centred. In the British Isles sporadic cases also cropped up in the years prior to the war, but owing to the then slight development of dye factories they were few in number and did not attract much attention.

Among the cases which I include is one in which the patient was operated upon by Mr. Burgess in 1911 for a papilloma. It is particularly interesting to recall that this patient was well until 1928, a period of seventeen years, when he again showed symptoms and a papilloma was treated by cystodiathermy in the Ancoats Hospital. It is hardly to be believed that this tumour was a recurrence of a growth which had lain dormant for seventeen years. It would appear more likely that it was a fresh tumour occurring in a patient who was unduly susceptible, either naturally or as a result of his occupation. Yet it is not unknown for patients to have recurrences late, and Simon[18] reports instances where he has seen death occur from local recurrence seven, ten, and twelve years after operation.

The patient was submitted to me for inspection by Mr. Heritage, and now remains under my care and treatment in the event of further relapses.

A somewhat similar case was seen recently suffering from cystitis, haematuria, and obstruction to micturition. In 1915 this patient had an ulcer the size of a half-crown excised from a situation above the left ureter by Mr. Hey, and the section was reported as carcinomatous. At the present time he is under my care for a small villous-like structure lying just above and to the left of the urethral orifice, the bladder itself being mildly inflamed. There is some thickening of the left ureteral bar—probably at the site of the original operation—which, however, is not regarded as neoplastic.

Prior to the onset of a vesical neoplasm in these aniline workers there is a premonitory period in which the patient suffers from symptoms of cystitis, such as frequency of micturition, with strangury, and sometimes haematuria. The haematuria is generally terminal, and may be suggestive of tumour formation. This stage of cystitis may be the forerunner of a neoplasm, but if the patient changes his occupation the symptoms sometimes disappear and no tumour occurs. Occasionally, in spite of a change in employment, a growth ensues, and this may happen several years after the factory has been left.[19] It is hardly necessary to emphasize the importance of cystoscopy during this prodromal stage. It is undertaken so that the neoplastic degeneration, if it occurs, may be caught early. The cystoscopic picture I have found to differ from that seen in a septic cystitis, particularly in the absence of exudate. The bladder shows a bright erythema with a tendency to mottling. It is more brightly red or pink than the usual colour in cystitis. Its surface is free from exudate, and apparently the superficial epithelium is not exfoliated. Perhaps this accounts for the brilliant appearance of the mucosa. There is, however, a fair degree of evenly distributed oedema, though I have not observed the bullous variety.

In addition to these 6 cases, I have, through the courtesy of Dr. Wignall, had the advantage of studying the records of 9 other cases which have occurred in dye workers in this city since 1920. As Dr. Wignall is reporting these cases at the discussion on industrial cancer I shall not further refer to them, save to remark on the long period of contact with the dye which appears to be necessary. There is one case which developed cystitis after eight to ten years, but in this small series all those who have developed growths have had twenty to thirty years of service.

A not uncommon situation for the development of a papilloma is the vesical orifice, and I have seen 4 cases in which the primary growth occurred there. Secondary growths are not uncommon here also, and are probably accounted for by a large frond getting caught in the meatus during micturition and forming a "kiss cancer." Such patients are liable to suffer from intermittency of the stream and even acute retention. Growths situated at the bladder outlet cannot be reached by the usual catheterizing cystoscope, and to meet this difficulty Swift Joly has introduced an ingenious instrument capable of retrograde vision and retrograde treatment. Prior to the invention of this instrument I have had to open the bladder to destroy a tumour surrounding the urinary outlet. Indeed, such tumours situated near the neck may still have to be submitted to cystotomy because instrumentation, however gentle, may cause bleeding sufficiently severe to debar endoscopy. I have used Joly's instrument with much satisfaction on several cases, but on occasion I have found it difficult to approach the urethral margin sufficiently closely, and have therefore had to complete its work with the posterior urethroscope. More than once I have had to treat implants actually occurring within the proximal half of the posterior urethra, and these also may be reached with the posterior urethroscope. It is an interesting fact that they are unknown in the anterior urethra, where wart formation is almost invariably a complication of gonococcal infection.

A papilloma of the bladder is itself occasionally secondary to one in the upper urinary passages. Of this I have seen two instances. In the first a small papilloma was seen protruding from the ureteric orifice into the bladder. An illustration of this I have published elsewhere.[20] In a second case a papilloma of the ureter was removed, but the tumour recurred in the adjacent ureteric stump, and also in the bladder. In the latter organ it grew from the actual lips of the ureter. I excised the greatly distended and thickened lower end of the ureter, together with an area of bladder surrounding its opening.

Implants from the kidney have also been known to grow in the bladder, and Murchison[21] records one in which there were papillomata in each of the renal pelves and an implant at the orifice of each ureter. Bland-Sutton[22] states that papillomata of the renal pelves, though rare, are often bilateral. This, however, I have not corroborated from the literature. In the museum of the Royal College of Surgeons[23] there is a specimen showing a papilloma attached by a narrow pedicle to the neck of the bladder immediately above the urethra. One end of the right kidney was occupied by a soft spongy mass of cancerous material.

I remember a case where I removed the kidney for papillomatous disease of the pelvis some eleven years ago. I was perhaps less alive then than now to the advisability of removing the ureter together with the kidney. The patient had a haematuria of moderate severity several days after the operation, which caused me some anxiety, as it suggested that I might have left a papillomatous secondary in the ureter. In spite of prolonged observation, however, this patient did not develop further trouble.

Treatment.

The treatment of small benign papillomata was revolutionized in 1910, when Beer[24] conceived the idea of applying the then comparatively new high-frequency current to their destruction. For a time after their introduction opinion wavered between the monopolar and bipolar diathermic currents, but it finally settled down to the latter so far as this country is concerned, and is now, I believe, universally employed here, though Beer[25] in America has recently emphasized some advantages of the Oudin monopolar current. The difficulties of adequate insulation are greater with the Oudin than with the d'Arsonval current. This probably accounts for the preference shown for the latter on this side, as with the small calibre cystoscopes which we favour these difficulties cannot be overcome.

Technique of Bipolar Diathermy.

A large flat indifferent electrode is closely applied to the sacrum or thigh, and the active electrode, a fine, insulated copper wire with a platinum terminal, is passed through the catheterizing cystoscope for application to the growth. These electrodes connect with the terminals of a diathermy apparatus, and the papilloma is burnt piecemeal under cystoscopic vision. The movements of the active electrode are controlled in the same way as the catheter is moved for ureteric catheterization. When commencing the operation the surgeon selects an area to apply his electrode. It is prudent not to start on the easiest areas first, but to reserve them until later, for the operation becomes increasingly difficult as it proceeds, and it is as well to destroy the more inaccessible portions of the tumour before the bladder conditions become unfavourable, leaving the easier ones to the end. A weak current is employed in the first instance and is gradually increased in strength, the surgeon judging the necessary strength by its effect on the growth and not by the reading on the ammeter. When the current first runs a gentle swirl is observed amongst the fronds of the papilloma, followed by the formation of a few minute air bubbles. A blanching of that portion of the growth in contact with the electrode is soon visible, and it extends till the tip is surrounded by a whitened ring of coagulum, one or two millimetres in width. The current may now be broken and a fresh situation for the electrode chosen, the treatment being repeated at different points till the whole surface has been desiccated, when the treatment is suspended for a period to allow the separation of the sphacelus.

A slough should be given time to separate. Between two treatments I am accustomed to allow three or four weeks to elapse. At the end of this period a benign papilloma should be definitely smaller, should have separated its burned areas, and we should find that the parts which have survived lie on a lower plane, being recognizable by

their deeper and redder colour. Their surface appearance simulates that of fine healthy granulation tissue. If slough still adheres to the growth malignancy must be suspected. I am much impressed by this property of a malignant growth to retain slough on its surface after diathermy, and agree with Young[1] when he says, "the adherence of the slough to the surface of the tumour seems to be in direct ratio with the malignancy of the growth." Sometimes a growth is completely hidden by slough, though with the electrode you can generally displace the deposit and so expose the papilloma. Experience with these growths will show that this feature is one of the most certain evidences of malignancy which we possess. It is related to the tendency shown by bladders containing a malignant neoplasm to become septic and to remain so in spite of treatment.

An alternative plan is to apply the current rather fiercely for a longer time at one spot. When it has run for a short time it will be noticed that adhesion between the two has occurred. The electrode is now slightly withdrawn so as to elevate the papilloma from the bladder base. This little manœuvre lifts the lowest lying villi from the vesical wall, thus eliminating alternative routes by which the current may gain the indifferent electrode and concentrating it upon the pedicle. Heat is developed in greater or less degree along the whole course of the current between the two electrodes, but varies in intensity directly as the current density. It will be very intense at the point of the active electrode and least intense where it is spread out to reach the large surface of the indifferent electrode. Between these two lies the pedicle of the papilloma—in many instances a narrow isthmus. If alternative routes can be eliminated by means which I have already suggested, this pedicle must carry the whole current. The heat will therefore be high and the pedicle, if it is a narrow one, may be devitalized. The tumour will then in due course be cast free in the bladder and passed with the urine. I have witnessed this several times; thus a growth 1¾ inches in length and half to three-quarters of an inch wide was passed through the urethra by one patient, whilst in another instance, through the cystoscope, I actually saw the papilloma lying free in the bladder cavity. In yet a third case a papilloma grew from within a vesical diverticulum. Diverticulum and growth should have been excised by open operation, as was done in a similar case which I shall describe shortly; but the patient being in feeble health I resolved to employ diathermy to the papilloma as it lay in the diverticulum. This I did vigorously, with the result that, for a period of two years, during which the patient was under observation, no recurrence was seen, and I believe that destruction of the growth was accomplished through overheating of its pedicle as just described.

Large growths, either because they are fast-growing and therefore of high cellular activity, or because they have been long in the bladder and have had time to degenerate, are more likely to have undergone metaplasia than small ones, and size is therefore in favour of malignancy. A bulky growth hampers diagnosis, but it also impedes treatment, whether endovesical or open. When a large neoplasm is benign, one must decide whether to set out on a protracted course of diathermy or to open the bladder and, by the use of a combination of excision and burning, to destroy the main mass of the tumour. There are disadvantages with each method, for, on the one hand, prolonged and repeated endovesical treatment is trying alike for patient and surgeon, whilst on the other hand is the danger of implantation, the prolonged convalescence, and the fact that the patient does not entirely escape subsequent cystoscopies and perhaps diathermies. If the growth is *malignant*, excision offers the only hope for its unfortunate host.

Open Operation.

Whilst the introduction of endovesical treatment marked a revolution in its own line, an advance scarcely less important has since been registered in the technique of the open operation. As you know, until recently it has been customary to proceed in the first place to a suprapubic cystotomy and then to attack the tumour from within the vesical cavity. This limited operation permitted the removal of the mucosa and other superficial layers of the bladder wall surrounding the base of the tumour. The intimate contact and adhesion of the bladder to extravesical structures prohibited a bold removal of the whole thickness of its wall, much less a wide resection. Moreover, as the lymphatics run in the deeper coats of the viscus and are absent from the mucosa and submucosa the avenues of spread for malignancy were left behind, and it is little wonder that recurrence was frequent.

It is largely due to the work of Bentley Squier[26] that the methods of mobilizing the bladder have been put on a satisfactory basis. In the operation which I practise, and which I have based on Squier's technique, a median incision extends from above the umbilicus to the pubis. By gauze dissection the lateral aspects of the bladder are raised from the pelvic parietes and the dissection is continued in an upward direction till the peritoneal reflection is encountered and the peritoneum is stripped off the fundus of the bladder. This order of progression is adopted with a view to reaching the urachus late. Where the urachus leaves the bladder the peritoneum is closely adherent to both these structures. When the urachus is divided the peritoneal cavity is entered and the opening is used for the investigation of the peritoneal surface of the bladder and for the determination of the presence or absence of pelvic and iliac secondaries. The peritoneum is then closed and the remainder of the operation is strictly extraperitoneal.

After this stage the patient is placed in the Trendelenburg position and the dissection (in the absence of perivesical inflammation or adhesion) is rapid and easy, and gauze stripping can completely mobilize the viscus, leaving it attached only by the structures around its neck. Deep in the pelvis two bands—the uretero-sacral bands—pass backwards and outwards. They contain the ureters, which are thus located but not necessarily seen, and can easily be better exposed if the circumstances demand it. When required the dissection is continued till the prostate and seminal vesicles are exposed.

Not until the bladder has been sufficiently freed is it opened. The organ is drawn forward over the pubis and the incision is made into the posterior wall of the viscus, but its exact site is chosen with reference to the position and dimensions of the growth which have already been ascertained by cystoscopy. The neoplasm is removed together with a generous area of bladder wall. The division is effected by scissors, the work being conducted from within the viscus so that the tumour shall be in full view. Owing to the customary situation of these tumours it will often happen that the area removed will include a ureteric orifice. When the incision is complete the ureter will therefore anchor the excised growth. Being fixed for identification by a pair of forceps this will be the last structure calling for division. It will subsequently require reimplantation, though sometimes when this is not possible satisfactory results may be got by ligaturing it, as recommended by Judd and Harrington.[27] The kidney then gives no trouble unless it is severely infected. Many kidneys are in any case dilated and valueless.

Squier[28] has, however, shown that the area of bladder to be excised cannot be dismissed as lightly as the above description might indicate. Having described the lines of lymphatic drainage within the bladder wall, he has demonstrated that the area to be removed must be regulated by a knowledge of these drainage routes if recurrence is to be avoided. Space forbids me to go into the subject of these routes in greater detail. Frequently it happens that a half or more of the viscus must be removed, yet when healing is complete it is astonishing how rapidly the bladder regains its full capacity, even after an extensive resection.

That this operation is superior to its forerunners is unquestionable. In none of my cases has there been trouble from deep pelvic suppuration due to the extensive dissection and soiling of the wound with urine, the healing of the posterior surface of the bladder being, so far as can be judged, prompt and more easily obtained than that of the anterior. The operation becomes more formidable when ureteric resection has to be practised, however, and it carries a higher *immediate* mortality. Resection of the

ureter is not necessary when growths originate at a distance, but, as is well known, the areas above and external to its orifice are the sites of election for these tumours. In my experience papillomata arising high on the bladder walls run a very benign course, and I have seen several which have gone for ten years or more and remained small and benign, and therefore good subjects for cysto-diathermy. Yet when malignancy does occur excision has to be exceptionally free because the vesical apex is a watershed for the lymphatic fields, and the routes of dissemination are therefore numerous. For this reason, though the growth involves the most accessible part of the bladder wall, the *late* operative results are not so good as those following operation on growths arising at the site of election (Squier[24]). Moreover, the dome of the bladder "resembles the silent area of the stomach, the greater curvature, where tumours occasionally become large before localizing symptoms appear" (Scholl[28]).

The preliminary mobilization of the bladder which I have described is an invaluable method of attack in other operative procedures on the deeper-placed areas of the viscus—as, for example, when a diverticulum has to be removed or a stone in the lowest segment of the ureter calls for open operation. In one of my two cases of papilloma springing from within a diverticulum the whole sac was excised together with the papilloma. In another patient, of whom *I have already spoken*, the lower end of the ureter contained a recurrent papilloma together with an implantation in the bladder at the ureteric outlet. The ureter was removed by a similar exposure, together with an area of bladder surrounding its orifice.

Whatever method of open operation is employed the tendency for implantation to occur in the wound itself must be guarded against by *protecting all* exposed surfaces with tetras and swabs *soaked in silver* nitrate solution (1 *in* 1,000). The greatest care is exercised *in the handling* of the growth itself, and every preparation which can shorten the *time that it is exposed* is undertaken *before the bladder* is opened. Here again the advantage of the preliminary wide mobilization of *the organ is evident*. In the final toilet the wound is again sponged with silver nitrate 1 *in* 1,000, resorcin 50 per cent. (Young *and* Davis),[4] or alcohol (Beer), according to the choice of the surgeon.

This is a large and severe operation, yet it represents a *material improvement on its* predecessors. When the tumour is small it is less difficult, but when it is large the difficulties are much increased. The fact which must strike one, of course, is the wide difference between the treatment of a small benign and a large malignant growth, the one being successful and rapid, the other very dangerous and very difficult. The problem therefore lies in getting the cases in their early stages as *soon* as ever the earliest haematuria gives warning of a lesion in the urinary tract which calls for cystoscopy. It is the relative infrequency of bladder tumours which militates against their early reference to the surgeon, for the importance of immediate examination *is not* borne home so easily to the medical attendant. "Had symptomless haematuria been as common as the acute appendix, it would have gone *through the same phase* as that condition experienced twenty years ago, and would now be invariably submitted to immediate cystoscopy, *just as the* acute abdomen is promptly submitted to laparotomy."[29a]

THE COMBINATION OF COLLOIDAL LEAD SELENIDE (D4S) AND RADIUM IN THE TREATMENT OF CANCER.

BY

A. T. TODD, M.B., M.R.C.P.,

AND

H. M. ALDWINCKLE, M.B.,

CANCER RESEARCH DEPARTMENT, BRISTOL ROYAL INFIRMARY.

In view of the recent increase in the use of colloidal lead selenide (D4S, British Drug Houses) in the treatment of cancer it is considered that the findings to be narrated should not await the second edition of our *monograph*. *This early report is sent out in the hope that other centres may avoid* the regrettable result of incorrect combination of this preparation with radiation.

We found that therapeutic *x* radiation subsequent to administration of D4S was nothing less than disastrous. Five cases were so treated, and the growth of the neoplasm appeared to be promptly and markedly stimulated. The combination of these two methods of treatment was considered to be dangerous, and a warning was given.[1] Two of the cases were as follows:

Case 1.—Male with inoperable carcinoma of lip and involvement of *submaxillary* glands. He was treated for five months with D4S, which resulted in increased feeling of well-being, gain in weight, fairly marked reduction in size of the growth with disappearance of the glands. Then the case remained stationary, and as the patient had had as much lead as we thought advisable we decided to try the effect of *x* radiation. He had received only half the usual carcinoma dose when it was found that rapid growth had extended into the tissues of cheek and jaw, and fistulae developed within two weeks. More lead was given, and the growth appeared to be checked, but by this time there was a large ulcer with much sepsis. *Ultimately* he died, apparently of sepsis, for there were no metastases.

Case 2.—Young female with large medullary carcinoma of breast. After five months of treatment this case was considered to be operable as the growth had become sharply circumscribed, much smaller, and glands had regressed. However, we decided to try *x radiation instead*. By the *time half the dose* had been given the mass was very *much larger*. The radiologist considered this to be oedema at first, but very shortly widely spread nodules in the skin of the chest and consolidation of the *underlying lung* dispelled optimism. After *improving* on D4S enough to be a fair operable risk the patient died of general carcinomatosis within six weeks of commencing *x* radiation.

In three other cases, with variation only as regards site, we had *similar results*—stationary or diminishing carcinoma began to extend quickly immediately *after x* radiation.

Later, when radium became available, we had a very similar experience. Some cases, not responding to treatment with D4S, were treated with radium. Marked oedema, shortly followed by necrosis of the tissues around the growth and sepsis, was the result. Two of these cases are worthy of note, for they appeared to give a clue to success in the combination of the two methods of treatment.

Case 3.—Male, recurrence of carcinoma of lip in submaxillary glands. He had been treated with D4S for three months, and had gained in strength and weight, but though the masses had become so soft as almost to fluctuate they were steadily growing. On the advice of one of the leading radium workers, who saw the patient and advised the dose and its application, radon was implanted in screened seeds of 50 per cent. strength. Oedema and necrosis followed immediately, and fungation into the pharynx

threatened to end the case. We decided to try to arrest growth with D4S, and gave the man his usual dose. He had had this amount for about three months, and experienced very little reaction, but after the radon there was severe focal reaction, and the dose had to be diminished to one-fifth. Thus, in this case, as in others, we have found that radium increases the local reaction to colloidal lead selenide.

FIG. 1.—Control mice, no treatment. All implanted from same tumour on May 28th. Scale throughout is one-fourth.

Case 4.—A female with recurrence of carcinoma of breast; two main masses were present, one above the clavicle, the other adherent to the ulnar trunk in the arm, causing anaesthesia dolorosa. She, too, was seen, and advised a dosage by the same authority; it was intended to implant two half-strength seeds into each mass—that is, half the dose for an untreated case. By error, only one seed was implanted into the supraclavicular mass—that is, one-quarter the usual dose—and this mass promptly disappeared. The brachial node was implanted with the other three seeds—that is, three-quarters of the usual dose; it became larger, and soon afterwards extension to the axilla and the pleura ended the case.

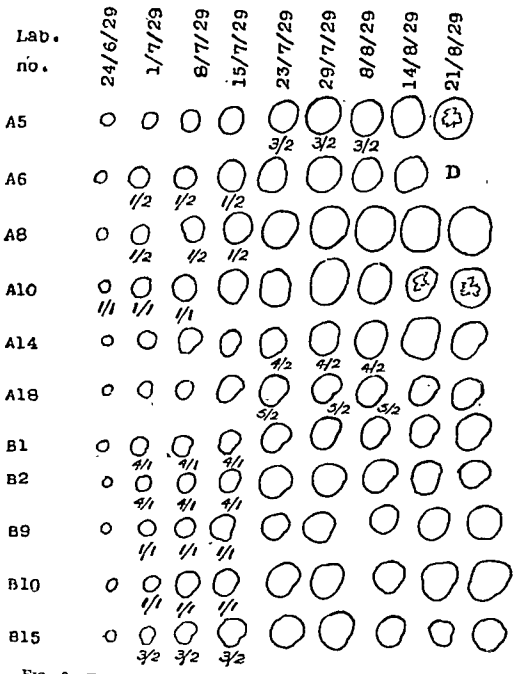

FIG. 2.—Treated with D4S first. Series A received 0.3 c.cm., B 0.4 c.cm. Radium dosage noted in the same manner as in Fig. 3.

A full description of the dozen cases which received therapeutic x radiation or radium after the administration of colloidal lead selenide would make very dismal reading, as it would be a repetition of the four cases recorded above. The only hint of success was the supraclavicular mass which received one-quarter of the calculated dosage. It would appear that D4S increases the sensitivity of cancer to x radiation and radium, and, secondly, that radium increases the sensitivity of the cancer to D4S. Other cases, treated at varying but longer intervals after x rays or radium, show that this sensitization is temporary; after an interval of six weeks or longer there is no evidence of unusual reaction.

It was decided that no more trial of the combined method should be made before a better technique should emerge from animal experiments. Mice were implanted with the Twort carcinoma. Some were not treated at all (Fig. 1); some were given intravenous injections of D4S in amounts less than sufficient to produce any decided result, then we applied radium (Fig. 2); still others were treated with radium first and given similar amounts of D4S afterwards (Fig. 3). Variations in exposures to radium and in the dosage of D4S are noted in the text. The radium was radium bromide, 1 mg. screened with 0.6 mm. of gold. It was applied to the surface over 5 mm. of compressed cotton-wool. In some cases two similar needles were used.

The result, as given in the figures, is much the same as we found in man. The reduced scale necessary for reproduction in the press, however, renders less evident the striking differences between the batches of animals. The tumours are very much larger than those of the untreated animals in the batch which had radium after lead, and, with one doubtful exception, all are advancing; while the

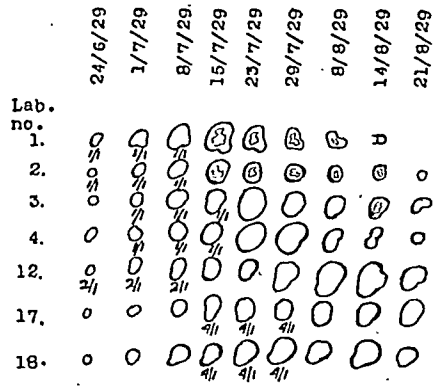

FIG. 3.—Treated with radium first. Dosage noted: 1/1 means 1 mg. for 1 hour, 4/1 means 1 mg. for 4 hours. Nos. 1 and 2 received 0.5 c.cm. D4S; Nos. 3 and 4, 0.4 c.cm.; Nos. 12, 17, and 18, 0.3 c.cm. afterwards.

tumours treated with lead after radium are diminishing in size, with one doubtful exception.

The result of one experiment should be accepted with reserve, but when, as in this case, it is completely in agreement with the therapeutic trial in man, its conclusions are strengthened. It is hoped that this paper may limit the number of unfortunate results in other centres. Those workers who have visited our clinic have been told that we allow an interval of four to six weeks after radium before starting colloidal lead selenide, and that we give very small doses of D4S if a patient has had any radiation within three months.

To attempt to explain these findings with the help of our inadequate knowledge of the pharmacology of lead and selenium would be foolish. It is possible that secondary radiation from the lead in and around the neoplasm might be a partial cause—that is, if secondary radiation is really of more than academic importance. It is more likely that the selenium, amongst other properties being markedly a photosensitizer, might sensitize the surrounding tissues to radiation. The latter explanation would be more in agreement with the severe peripheral oedema and necrosis which has followed radiation on tissue previously treated with lead selenide.

Further experimentation is being carried out here. If our conclusions become substantiated it is claimed that a further advance is likely in the treatment of cancer, for it is considered that colloidal lead selenide increases the susceptibility of the neoplasm to radiation, and that a dosage of radium of about one-fifth of that advised at the present time will be about the optimum.

Conclusion.

In the meantime it is strongly recommended that x radiation or radium should be applied with extreme caution, if at all, in cases of cancer which have been treated recently with colloidal lead selenide (D4S).

We have to thank Dr. J. A. Murray for Twort carcinoma and Professor Sidney Russ for gifts of radon. The expenses of this research have been met by the Bristol Royal Infirmary Cancer Research Fund.

HYOSCINE AMNESIA IN LABOUR.

A RECORD OF 24 CASES TREATED BY HYOSCINE ALONE.

BY

DAVID R. JENNINGS, M.B.N.Z., F.R.C.S.ED.,

SENIOR RESIDENT MEDICAL OFFICER, QUEEN CHARLOTTE'S HOSPITAL.

AN outcome of the suggestion that the morphine used in the twilight sleep method was responsible for the asphyxia or oligopnoea in some of the newborn has been the development of a new technique whereby amnesia is produced by hyoscine alone. It was devised by Dr. Bertha Van Hoosen of Lyola University, U.S.A., and consists in giving 1/100 grain of hyoscine hydrobromide as soon as labour is fairly started. Thereafter two more 1/100 grain injections at half-hourly intervals, followed by a similar injection of 1/100 grain every two hours for as long as labour lasts.

This treatment was brought to our notice by Dr. Cargil of Ottawa—a past resident of this hospital—who had tried it on several cases with success. At the instigation of Mr. Lane Roberts this treatment was carried out on 24 cases at Queen Charlotte's Maternity Hospital in July last. The treatment was applied to a sequence of cases where no evidence of any circumstance contraindicating normal delivery was present. This definition covered all patients who had been under treatment for albuminuria during pregnancy, for large doses of hyoscine diminish secretions and throw an added strain on the kidneys.

Analysis of Cases.

Of the cases treated, 16 were primigravidae and 8 were multigravidae. Their ages varied from 20 to 37 years. All except one were occipito-anterior presentations; the one exception was a breech presentation with extended legs, in a multigravida.

The average total duration of labour for primigravidae was 19 hours 43½ minutes; the shortest 6 hours 50 minutes, and the longest 42½ hours. The average total duration of labour for multigravidae, on the other hand, works out at the rather large figure of 20 hours 47 minutes. The shortest was 7 hours 40 minutes; had it not been for the fact that one massive patient had gone 22 days over her dates, producing a 9 lb. 12 oz. post-mature baby after a total labour of 77 hours 20 minutes, the average time would have approximated 9 hours, which is quite a favourable figure. The average second stage for primigravidae was 2 hours 16½ minutes, and that for multigravidae was 41½ minutes.

Twenty of the patients had normal deliveries; 2 patients required the application of low forceps, and in one case the head was assisted over the perineum by the use of 2 units of pituitrin. The breech with extended legs was treated by bringing down one leg and flexing the other at the knee-joint when the cervix was fully dilated. Open ether was administered with apparent safety and ease to the three cases requiring assistance.

An interesting feature of this treatment was the fact that the babies at birth showed signs of active life rather more readily than in normal cases. All were born alive, the majority presenting a high pinkish hue on delivery. Where the cord was round the neck, having to be cut or slipped over the child's head, there was no more blueness than is usual. The babies in the two forceps cases were "left alone," and they recovered just as ordinary forceps cases do. The baby with extended legs was born in white asphyxia. The treatment of masterly inactivity and a warm bath soon revived it.

No trouble was experienced with the third stage of labour. The average duration for all cases was 15 minutes 12 seconds. The loss of post-partum blood was small, the average being 5⅔ oz. The highest loss was 10 oz. and the lowest 3 oz.

When to Start.

The best time to give the initial injection of 1/100 grain of hyoscine to primigravidae was found to be when the cervix was taken up and dilated one finger. This must be associated with good regular pains, or the institution of the treatment may tend to delay labour rather than augment the pains. Should the former happen, it is better to wait an hour or so longer, until regular pains return, before giving the second injection, which normally should be given half an hour after the first.

The choice of time for multigravidae was more difficult to determine. They should be started early, as soon as they have definite pains, which must be felt and timed. Dilatation of the cervix may be deceiving, especially if the presenting part is low, for what is sometimes called a "multips os" may be mistaken for commencing dilatation of the cervix. Hyoscine treatment tends to quicken labour, hence if the injections are started late, amnesia may not be produced in a short labour. Most patients remember receiving two injections; so total amnesia does not start until an hour after the beginning of the treatment, though the memory of pains is probably lost earlier.

Course of Treatment.

The effect of the hyoscine becomes moderately noticeable after the second half-hourly injection. The patients enter that state which is so aptly termed "dopy." Compared with a normal patient there is a sharper distinction between the actual pains and the period of quiescence. The pains are characterized by a varied restlessness, some patients attempting to get out of bed. The period of quiescence is spent in quiet sleep. The pupils become dilated and the lips and tongue dry. Either at this time, or later, is noticeable a slight cyanotic flush, which may deepen in colour with subsequent injections, and is more noticeable during a pain.

The massive effect of the three half-hourly injections is not so marked as might be expected. The patients are not sunk in deep unconsciousness. They can be roused from their state, can give their names, and recognize common objects. It is usual for the memory test to be lost here, and it remains so until the end. The recognition test of an object such as a pen may be lost with subsequent injections. Its loss is certainly an indication that hyoscine is acting powerfully, and its early loss may incline one to lessen the dose or prolong the interval between doses; but the mere loss of the test does not seem a danger signal unless it be associated with a deep unconsciousness and stertorous respirations. None of the cases caused any alarm in this direction.

Restlessness, which rarely encroaches upon the interval between pains, is of varied quality. Rarely is it extremely violent. Only one of the patients—one whose build and strength magnified the restlessness—gave any real trouble. Most of the movements are best termed restless, and in some cases a slight deepening of the colour of the cheeks or a movement of a limb may be all that indicates the presence of a pain. The vocal organs may be used; but the voice is rarely raised above a moan or subdued muttering.

As long as the pains continue satisfactorily the two-hourly injections should be continued. Should they weaken or pass off it is better to prolong the interval before the next injection is given; but this is occasioned rarely when the treatment is started at the optimum time.

Here it may be noted that it is essential that the cases be under constant supervision throughout the treatment. A careful watch should be kept upon the bladder, as most patients require catheterization one or more times,

depending on the duration of the narcosis. Fluids, particularly milk, may be administered by the mouth. Restraint may be needed, but the patients are amenable to kindly yet forceful orders. Mechanical restraint of the arms may be required during the actual delivery in order to avoid a tear of the perineum or the soiling of the sterile clothes; but the perineum may be stretched and the "occiput flexed" without any added discomfort to the patient.

In view of the occasional idiosyncrasy sometimes found in using hyoscine it will be of interest to recount that while no patients were found intolerant of the drug, two patients exhibited definite hallucinations, which, curiously enough, did not appear until immediately after the delivery of the placenta. This condition gave rise to no anxiety. It disappeared with the dawn of consciousness, and all the mothers have since been normal.

Results.

The most interesting part of the whole treatment is visible when consciousness returns some two to three hours after delivery. The mothers look remarkably fit and well. There is hardly anything in their facial appearance to suggest that they have been through a labour and delivered of a child. Most remain oblivious of the fact that they possess a baby until they are informed or happen to place a hand upon the abdomen and find the contour changed. Then their smiling thanks are worth any added work entailed by the accoucheur.

Complete amnesia was obtained in 20 cases. One primigravida, who had had three injections, only remembered six pains and the birth of the baby, which was painless. One of the patients, delivered by forceps, only remembered the mask being placed upon her face. This island of memory, similar to two other small islands of memory in the two remaining cases, seemed directly attributable to a delay in giving the last injection owing to an apparently imminent birth. Experience showed that the last injection might be given in safety, even when the head was distending the perineum. In patients under the influence of this treatment the *vis a tergo* seemed purely uterine, and the final extraordinary expulsive efforts were more or less lacking and not accompanied by increased abdominal tension. This often led to a relatively slow stretching of the perineum.

The Application.

Dr. Van Hoosen gives the lengthy name of "scopolamine-narco-anaesthesia" to her treatment; but in view of the rather unique narcotic and anaesthetic effects of hyoscine I venture to suggest that the name of "hyoscine amnesia"—or "scopolamine amnesia," if you will—would be more all-embracing and suitable.

Conclusion.

It has been stressed already that the patients must be under constant supervision. Apart from the usual nursing attendance, restraint may be needed for restlessness during the pains. Extra help may be required at the time of delivery, unless the patient is secured with suitable appliances, which limit the use of her hands and the tendency of her body to undo the left lateral position in which she has been placed. Against this can be placed the valuable assistance rendered by repeated kindly, simple, yet forceful orders. It is often the hefty type which causes trouble; the thin, nervous woman, for whom this treatment seems eminently suitable, rarely gives any trouble.

Advantages of Hyoscine Amnesia.

1. The treatment is simple to carry out.
2. There is a fair certainty of obtaining loss of memory of the delivery and of the worst of the labour pains.
3. There is no apparent ill effect on the child.
4. The treatment has a tendency to shorten labour as a whole.
5. There is no apparent increased tendency to the use of low forceps.
6. There is a shortening of the third stage of labour and a small loss of post-partum blood.

RESPIRATORY FAILURE DUE TO CEREBRAL ABSCESS.

BY

A. ANDERSON, M.B., CH.B., D.P.H.,

LATE RESIDENT MEDICAL OFFICER, MONSALL HOSPITAL, MANCHESTER.

AMONG the modern advances in medical science the pathology, diagnosis, and treatment of intracranial lesions occupy a high position, but the case of cerebral abscess described below presents some unusual features, and is, I think, worthy of being recorded. The following notes are taken from the case records.

H. R., male, aged 25, was admitted to Monsall Fever Hospital at 10.15 p.m. on May 2nd, 1929, certified to be suffering from meningitis. Several days previous to admission he had complained of left earache, but had continued at his occupation of fruit-market salesman. He returned from work at midday on the day of his admission complaining of severe headache and backache, and soon afterwards began to feel drowsy. When seen by his doctor he was thought to be suffering from meningitis, and was sent to Monsall Hospital.

On admission he was in a drowsy, semicomatose condition, and could be roused with difficulty, but quickly returned to his drowsy state. Both pupils reacted to light, but the left pupil was slightly smaller than the right one. There was no strabismus or nystagmus. There was slight retraction of the head and marked nuchal rigidity. The tongue was dry and furred, but the throat was clean. No rhinorrhœa or otorrhœa was present, and no tenderness was elicited over the mastoid processes. Kernig's and Babinski's signs were present. No albumin or sugar was found in the urine. Examination of the heart, lungs, and abdomen revealed no lesion. Temperature 100.2°, pulse 100, respirations 28.

May 3rd. Patient was drowsy; there was no delirium or irritability; he could be roused sufficiently to answer questions rationally, but only after a definite latent period; complained of suboccipital pain; pupils normal and reacted to light; no strabismus or nystagmus; no otorrhœa; Kernig's and Babinski's signs present; temperature 101°, pulse 104, respirations 23. Under local anaesthesia lumbar puncture was performed. The cerebro-spinal fluid was under pressure, and 40 c.cm. of slightly turbid fluid were withdrawn. Examination revealed numerous polymorphonuclear leucocytes, but no organisms were found in stained films, and cultures on blood agar yielded no growth.

May 4th. Patient not so drowsy and nuchal rigidity not so marked; complained of severe frontal headache; herpes of upper lip and pinna of right ear; temperature 98.6°, pulse 68, respirations 20.

May 5th. Condition unchanged; no evidence of aural lesion; headache continued; temperature 99.4°, pulse 76, respirations 20.

May 6th. Severe frontal and suboccipital headache; no head retraction, but definite rigidity of neck muscles; slightly drowsy; no incontinence; pupils normal; no mastoid tenderness, but slight reaction to hydrogen peroxide in right ear; temperature 99.6°, pulse 56, respirations 22. Lumbar puncture was repeated, the cerebro-spinal fluid was not under pressure, and 15 c.cm. were withdrawn. The fluid showed very slight turbidity, but no organisms were found, despite the continued presence of polymorphonuclear leucocytes. The visiting aural surgeon was asked to examine this case, and he reported as follows: "Both tympanic membranes opaque, but no pus in either and no bulging. No indication of aural cause for meningeal condition." The following day the condition was unchanged; temperature 100°, pulse 56, respirations 20.

May 8th. General condition showed slight improvement; temperature 98°, pulse 52, respirations 24. On May 9th the nuchal rigidity and headache were less; he was rational in conversation, but not taking much interest in his surroundings; there was no paralysis or paresis; pulse still slow; temperature 97.8°, pulse 52, respirations 20.

May 10th. At 10 a.m. I arrived at the ward in response to an urgent call to find the patient unconscious and cyanosed. Respiration had ceased, but the heart was beating regularly, though slowly. There was general spasticity of the muscles, but no twitching; both pupils were fixed, the right contracted and the left widely dilated; there was no strabismus, no nystagmus, and the superficial reflexes were absent. A gag having been inserted into the mouth artificial respiration was begun and the cyanosis rapidly disappeared. Strychnine and pituitrin were administered hypodermically. Gradually the limbs became flaccid, and both pupils were now dilated and fixed. Artificial respiration was maintained, but no attempt at natural respiration occurred, though the heart's action continued to be regular and forceful. While a careful watch was kept on the condition of the heart, artificial respiration was discontinued till the patient was "black in the face," but artificial respiration had to be started again. At the end of one hour the condition was unchanged. Cistern puncture

was performed, but the cerebro-spinal fluid was not under pressure, and only a few drops of clear fluid were withdrawn. No alteration in the condition followed this procedure. Despite the continued artificial respiration, an earthy cyanosis now appeared, both pupils were dilated and fixed, and the extremities cold and clammy. At 3 p.m. the heart began to lose tone, gradually became irregular, and, despite energetic stimulation, death occurred at 4 p.m. (six hours after cessation of respiration).

A post-mortem examination was performed on May 11th, and the following notes are extracted from the report.

"Brain: no evidence of meningitis; circumscribed abscess about the size of a walnut in left temporo-sphenoidal lobe; abscess cavity contained thick greenish pus with foul odour; abscess situated completely in the white matter, but a visible track led through the grey matter to the petrous portion of the left temporal bone; the white matter round the abscess for a variable distance showed marked softening, with scattered minute haemorrhages; ventricles not distended, and contained no pus; no cerebellar or pontine lesion.

"Left temporal bone: tegmen tympani discoloured and eroded; middle ear and mastoid antrum full of partially organized granulations; the mastoid process showed marked sclerosis of the bone, and the scanty air cells were filled with granulations; lateral sinus not involved; no evidence of spread of infection to cerebellar fossa; membrana tympani thickened but intact.

"Stained films of the pus showed numerous pus cells, Gram-positive and Gram-negative diplococci, Gram-negative bacilli, and short chains of streptococci. Films of the growth on blood agar plates revealed similar organisms; the streptococci were non-haemolytic."

The cessation of respiration must have been sudden in onset as the ward sister had conversed with the patient shortly before she discovered him in this state, and none of the other patients in the ward was aware of any change in his condition.

With the assistance of the family practitioner I made more detailed inquiry into the previous history of this case. On or about April 15th he had complained of earache, and had attended the Ear Hospital, where he was given some drops to instil into the ear. The condition apparently subsided, and he was in good health till the day of his admission to hospital. His wife reported that she had heard him say that he had "always been slightly deaf." The marked sclerosis of the mastoid process and its incomplete pneumatization suggest that the aural lesion was of longer standing than the history would suggest. No history of vomiting, vertigo, dimness of vision, diplopia, or even headache could be obtained. The necropsy findings point to the abscess being of some duration, and that the terminal condition was due to extension into the surrounding cerebral tissue.

Ransom[1] states that the respiratory centre is situated in the caudal part of the medulla oblongata. Landois and Stirling[2] discuss the question of an additional cerebral respiratory centre, but modern physiologists agree in placing the respiratory centre in the medulla oblongata. The work of Lumsden[3] shows that the mid-brain has no influence on respiration. On anatomical grounds the cessation of respiration in this case does not seem to have been due to pressure on the centre. Four days had elapsed since the last withdrawal of cerebro-spinal fluid.

Macewen[4] and others have described cases of cerebellar abscess causing pressure on the pons and cessation of respiration, but I have been unable to find any references to a similar condition occurring in a case of cerebral abscess.

I wish to express my thanks to Dr. D. Sage Sutherland, medical superintendent, for permission to publish this case.

NASAL DISCHARGE IN CHILDHOOD.*

BY

F. BRAYSHAW GILHESPY, F.R.F.P.S., D.L.O., M.R.C.S., L.R.C.P.,

HONORARY SURGEON, BIRMINGHAM AND MIDLAND EAR AND THROAT HOSPITAL.

For the purpose of this communication 50 children, under 14 years of age, have been selected; these, when first seen, had one symptom common to all—nasal discharge. The children have been kept under observation, with few exceptions, for two years or longer. The fifty children may be classified as follows.

Fifty Cases of Nasal Discharge.

	Cases.
A. Tonsils and adenoids previously removed; maxillary antrum infection present	23 (16)
B. Maxillary antrum infection present; no operation on throat previously; adenoids not present	9 (1)
C. Tonsils and adenoids removed; antral investigation negative; nasal discharge persisting ...	10 (8)
D. Required second or third operation on tonsils and adenoids to terminate nasal discharge ...	6 (4)
E. Atrophic rhinitis	2

The figures in parentheses indicate the number of cases in which otorrhœa or deafness was a symptom: 29 such cases are noted, or 58 per cent. of all cases. It is only fair to add that many of these cases came under my notice primarily for the relief of aural disease. Sinus infection was present in 32 patients, or 64 per cent. of cases, as shown in the table.

Class A.

In these cases nasal discharge had persisted despite an efficient removal of tonsils and adenoids. Cleminson, in 1921, put forward as a cause of the lack of attention paid to the sinuses in young children the great similarity between the clinical picture produced by sinus disease and that painted in almost every textbook as due to adenoid hypertrophy. Both conditions may give rise to the running nose, and probably in the 23 cases in this group the tonsils and adenoids had been removed with a view to the relief of this symptom among others. When first seen by me nasal discharge was present, and unilateral or bilateral antral infection was demonstrated by proof puncture. The presence of pus or muco-pus in the suction syringe or wash-out was the only positive criterion of infection accepted. In the majority of children I perform proof puncture of the antrum with a fine, straight trocar and cannula through the inferior meatus of the nose, having first inserted a probe covered with cotton-wool in 5 per cent. cocaine with adrenaline on to the selected spot for perforation of the antral wall. I have had no trouble from the cocaine. I would like to ask the question, Was it unnecessary in the first place to have advised the throat operation? Probably it was not, as, in my experience, the presence of an obstructed or septic nasopharynx is a hindrance to the cure of an infected sinus; for, as

* A communication to the Section of Oto-Rhino-Laryngology at the Annual Meeting of the British Medical Association, Manchester, 1929.

Cleminson very aptly expressed it, "These two conditions [infected adenoids and sinuses] play into one another's hands." In view, however, of our increasing experience of the frequency of sinusitis in children, the presence of pus in the nose should have put the operator on his guard and made him consider the possibility of sinus involvement.

In most of these cases, when I saw them for the first time the diagnosis was self-evident, pus being present in the nose, generally in the middle meatus. A boggy or polypoid anterior end of the inferior turbinate led me to suspect an antral infection in a few cases. Recent correspondence in the *British Medical Journal* showed a very active interest in this class of case, and, unless the general practitioner—who operates on a great number of patients for tonsils and adenoids—and otologists and laryngologists realize the pitfalls of sinusitis in children, great harm will be done to the prestige of the "tonsils and adenoids" operation. In my opinion local authorities who recommend removal of tonsils and adenoids in great numbers should especially heed this warning. Another pitfall which it would appear appropriate to mention at this juncture is that pus in the nose, without blood, may be due to the presence of virulent Klebs-Loeffler bacilli. I have been called to three such cases in the last year and introduced this point, as in two cases the patients were children of medical men and the true cause of the discharge had been unrecognized.

CLASS B.

This class is composed of 9 cases; they are perhaps interesting in that they were cases of sinusitis uncomplicated by the presence of adenoids at any time in their history, with a marked freedom from otological complications. As in the previous group, I have no wish to give my views on the treatment of antrum disease, but record my disappointment of the value as a curative measure of simple antral wash-outs by means of trocar and cannula, except in cases of recent infection. What particularly is in the forefront of my mind in this connexion is the question as to whether ethmoidal disease is common in young children. Not all of our cases of antrum infection clear up as we should like them to. Are some of these failures—often comparative—attributable to an unsuspected ethmoiditis? A recent transatlantic communication lays stress on this aspect of the subject, and bases diagnosis on *x*-ray appearances. The infallibility of this course cannot as yet be accepted, but the question which appears to arise is whether in every case of suspected antral suppuration an *x*-ray photograph should be taken before treatment is commenced, and studied with reference to all the accessory sinuses of the nose. The following case is illustrative of difficulty in both diagnosis and treatment in a small child.

The patient was an undersized child, aged 5, whose tonsils and adenoids were removed one year previously for obstruction and nasal discharge; the muco-purulent nasal discharge persisted. There was a history of bronchitis since an early age. In the radiogram both ethmoids were dim. An antral wash-out was negative, right and left. The nose was very small, and it was impossible to remove a portion of the middle turbinate. The discharge continued. Pure culture streptococcus vaccines were given.

Opinion appears to favour removal of a middle turbinate in such cases as a first step in treatment. This should answer well in a suppurative case, but would it be of any use in an early case of polypoidal degeneration of the ethmoidal cells? One question in connexion with nasal catarrh and sinusitis in children I should like to hear your opinion upon, and that is: Is it possible that obstinate sinusitis and polypus formation in young adults is a development of nasal trouble, apart from adenoids, that begins in childhood? If ethmoidal disease with polypoidal degeneration of the mucous membrane of the cells be present at an early age, can we hope by operation to prevent the bugbear of an adolescent ethmoiditis? From my own experience operation on such cases is safer, and the field of operation more clear if the patient is sitting up in a chair. I use Woodman's chair.

One of my first cases in practice was a child, aged 7, whose adenoids had been removed three years previously. The child still suffered from some nasal obstruction. Adenoids had been well removed. Luckily, from my point of view, I saw the child at the age of 11, when polypi were growing from the diseased ethmoidal cells. Such a case imprinted on my mind very forcibly the possibility of the early beginnings of ethmoidal disease, and increasing experience has confirmed this supposition.

CLASS C.

This class consisted of 10 cases of nasal discharge of indefinite nature which persisted after the tonsils and adenoids had been removed efficiently, proof puncture of the maxillary antra being negative. Several of these patients were plethoric-looking children with a persistent mucous nasal discharge and intermittent otorrhœa, mucoid in nature and coming from an anterior perforation. Broad nostrils, with excoriation of the surrounding skin due to nasal discharge, short cough, and husky voice were common to all. To me they answer to the description "catarrhal child." The nasal mucosa is thickened and congested in common with that of the pharynx and probably the respiratory tract. Some of these patients give a long history, almost since birth, of chronic colds. Neil Maclay has suggested that the susceptibility of the nasal mucosa to toxic products begins very early in life, and may be responsible for the catarrhal conditions in babies who have wet noses and a congested nasal mucosa, with nasal obstruction and respiratory difficulties. The frequency with which a history of colds dating from the first year of life can be obtained has been referred to by Dan McKenzie. I should like to emphasize the point from my own experience of these case-histories and many others, which show the early sensitization of the nasal mucosa to infection, with frequent spread to the bronchial tree during childhood. May I be excused for quoting from the following case record of Dr. Crosskey.

A boy, born August 22nd, 1922, was "snuffly" on September 2nd, and had bronchitis on December 1st of the same year. Later acute bronchial catarrh followed a cold. He had urticaria in September, 1923, and bronchitis in 1924, followed by nasal catarrh. In May, 1925, the tonsils were septic. He was seen by a physician in consultation in 1927, who advised removal of tonsils and adenoids, and thought cough might be partially due to asthma. The operation was performed by myself. Seen again in 1928, there was no improvement in the nasal catarrh and very little in the bronchial condition.

In this case there had developed an underlying vasomotor element, as evidenced by the development of asthma. I am precluded from dwelling on this aspect of the subject as a cause of prolonged nasal catarrh, but undoubtedly it has a place in the causation of the condition.

Maclay further suggested that the altered condition of the nasal mucosa brought about by "colds" in infancy favoured the growth of germ-life in the nose, and might lead later to a superimposed infective inflammation, probably spreading to the accessory sinuses. While watching one of these catarrhal children over a period of three years, and in 1928 having punctured both antra with negative results, I was surprised to find in 1929 that the nasal discharge which had before been mucoid had become muco-purulent. By radiography and by washing out I confirmed the presence of pus in the right frontal sinus. Such cases show their origin from a chronic cause rather than an acute one.

One patient in this group of ten cases had the well-known symptoms of a vasomotor rhinitis: attacks of tickling sensation in the nose, lacrymation, and copious nasal discharge. On washing out his antrum a large amount of pus was found. No cases could be traced as due to food proteins or animal emanations. Such cases are of importance, but apparently rare. As regards treatment for these children with a chronic catarrhal condition I am on rather unexplored territory; at present I direct treatment towards improving their general health. Three certainly improved greatly after courses of treatment by means of general ultra-violet radiation. Removal of tonsils and adenoids had not noticeably improved them. In this class are the cases with enlarged anterior and posterior ends of the inferior turbinates. Does removal of the posterior ends do any good? Is it still practised as frequently as formerly? Should the anterior ends be cauterized or removed to give better aeration to the nostrils?

Research on the chemical constitution of the blood in these patients may be a helpful line which I intend to investigate further.

CLASS D.

This consists of cases in which operations in the throat had been badly performed, and which cleared up after thorough removal of adenoids.

CLASS E.

Cases in this class are included merely to show the material on which this communication is based.

CONCLUSIONS.

The points which have appealed to me in reviewing these cases are:

1. That the presence of pus or muco-pus in the nose must suggest the possibility of sinus infection, although the presence of adenoids may produce the same picture.

2. That when dealing with infection of the maxillary antrum in children the possibility of ethmoid infection at an early age must be kept in mind.

3. That before deciding on any operative form of treatment of a child's nose or throat a careful history should be obtained. This may form a useful guide to prognosis:

PERSISTENT NASAL CATARRH IN CHILDREN.*

BY

DOUGLAS GUTHRIE, M.D., F.R.C.S.ED.,

AURAL SURGEON, ROYAL HOSPITAL FOR SICK CHILDREN, EDINBURGH.

PERSISTENT nasal catarrh, or, in scientific language, chronic rhinitis, is a common disease in childhood, and its causes are numerous. The foremost cause is, of course, adenoids, and the adenoid growth is of two varieties. There is, first, the large central tumour mass; and secondly, the type in which the lymphoid growth is spread as a sheet over the roof and posterior wall of the nasopharynx. It is this second variety which is more liable to cause nasal discharge, and the discharge may persist even after careful operation.

Another cause of nasal discharge in children is diphtheritic infection, and we have found it so common in the Children's Hospital that we take a swab from every case of nasal discharge. I mention this in passing in order to emphasize the importance of bacteriological examination.

As regards sinus suppuration, there is no doubt that the *antra* and ethmoids may become infected at an early age, as is proved by the work of Dean and others in America, and of Cleminson in London. My colleague Dr. Hall has followed up those researches and has kindly permitted me to quote his results, which are not yet published. He performed lavage of the antra in 85 cases from which adenoids and tonsils were to be removed. In 10 per cent. he found actual creamy pus in the antra, in 13 per cent. there was muco-pus, and in 27 per cent. the saline which he aspirated back into the syringe was turbid. The majority of such cases are curable by removal of adenoids, though a few cases may require operation on the antrum—namely, intranasal drainage.

The type of case which particularly interests us to-day is the little patient who suffers from persistent nasal discharge for which no apparent cause can be found. How frequently, for example, does one meet with children whose nasopharynges have been curetted on two or more occasions, without result!

Such patients suffer from nasal obstruction, as well as from nasal discharge, and I venture to submit that it is the obstruction, rather than the discharge, which constitutes the real cause of all the trouble. In fact, the so-called "persistent nasal catarrh" is caused by pyogenic infection in a narrow and poorly drained nasal cavity. In an obstructed nose secretions accumulate and readily become infected. The obstruction arises from arrested development of the nose and *nasopharynx*, caused by the *adoption* of a mouth-breathing habit at an early age. And how has this mouth-breathing habit originated? From a succession of head colds during the first few years of life. The sequence of events is as follows: recurrent attacks of acute rhinitis, nasal obstruction and mouth-breathing, arrest of nasal development, and eventually chronic rhinitis. The appearance of adenoids as an attempt to combat infection is a mere incident, though a fortunate incident if the adenoids are of the large tumour variety. Operation then effects a dramatic cure. But frequently there are no adenoids, and, furthermore, in at least 20 per cent. of cases of adenoids of the second diffuse type operation fails to cure the discharge and obstruction. This heterodox view, that nasal stenosis is the essential lesion, is borne out by the results of treatment.

The object of treatment must be to restore the patency of the nasal passages. Naturally one must deal with any cause of obstruction which one discovers. Adenoids must be removed, and I agree with Dr. Dan McKenzie that the adenotome is a more accurate and scientific instrument than the curette.

Enlarged turbinals must be reduced by partial removal, and special attention paid to enlarged "posterior ends." I have never discovered posterior ends in children under the age of 6, though they are not at all uncommon in older children.

As regards deviation of the nasal septum, this cause of obstruction is, in my experience, rather rare in childhood, apart from deviation directly due to injury. The deviation involves, as a rule, only the cartilage and not the bone. There need be no hesitation in performing a limited submucous resection, and I have never seen deformity follow operation when care has been taken to remove only sufficient cartilage to relieve the nasal stenosis.

There remains, however, the large group of patients who show no obvious cause of the nasal catarrh, although the entire nasal cavity may be smaller and less developed than it should be. What can be done for those little patients?

Regular removal of the muco-purulent secretion is the first essential. In babies a simple suction apparatus (*mouche bébé*) is useful. Older children must be taught how to blow the nose (by the open method, not by grasping the nose), although this is a difficult task for teacher and pupil. Local applications may follow this cleansing regime, and one of the best is the French preparation gomenol, which is used in 5 per cent. solution in olive oil, and dropped into the nose with a pipette.

As regards internal treatment, the "catarrhal" child derives benefit from sodium bicarbonate in large doses. I cannot explain this action, but the free use of such an alkali, by the mouth, is of great value in middle-ear suppuration, as well as in chronic rhinitis.

The so-called "catarrhal" and thickened mucous membrane may often be restored to normal by the method of "diastolization" introduced by Gautier in France five years ago, but only recently adopted in this country. The procedure is virtually a means of massaging the nasal mucosa by the expansion and dilatation of a thin hollow rubber bougie, connected to an otomasseur.

The dental condition is of some importance. When the upper dental arch is narrow and the teeth crowded it may be desirable to fit an expanding denture composed of two halves. This aspect of nasal obstruction in children has perhaps been unduly stressed by our dental colleagues, but it certainly deserves attention in selected cases.

Most important, however, is the restoration of the perverted respiratory function by systematic re-education. Breathing exercises are indispensable, but in carrying out the exercises, expiration, as well as inspiration, must be nasal. It is essential to insist on this, as one often finds that the teacher encourages children to take a deep breath through the nose and then let the air escape by the mouth. This is, of course, quite an unnatural method of respiration. It is even worse than the method sometimes adopted after adenoid removal—namely, no instructions and no exercises at all!

By such methods, conducted with diligence and care, the patency of the nasal airway may be gradually restored, and as the patient loses his mouth-breathing habit and acquires the normal manner of respiration by the nasal route, the nasal discharge will disappear.

*A communication to the Section of Oto-Rhino-Laryngology at the Annual Meeting of the British Medical Association, Manchester, 1929.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

ASTHMA AND URTICARIA.

THE following case, in which urticaria and asthma appeared in a patient suddenly and simultaneously, is interesting in view of the connexion many believe to exist between the two conditions.

On September 10th I was called to see a married woman, aged 81. I was informed that she had been perfectly well until half an hour before, when suddenly, on preparing to get into bed, she had experienced a feeling of great constriction round her waist, and of suffocation. Her hands and arms felt as if they had "gone to sleep," and she had an unpleasant sensation of tightness over the temples.

At first I was under the impression that the case was one of cerebral haemorrhage. The patient had made one abortive attempt to vomit, was very restless, and her hands were continually moving. On the other hand, the pupils were normal, the pulse 80, and the mind quite clear. The face was flushed, and the patient continually drew my attention to her hands, which were very red and hot, affirming that she felt as though they were "going to burst." Whilst I was observing her the breathing became wheezy, and on examining the chest I heard wheezy rhonchi, such as occur in association with asthma, but although the respiration was a little hurried there was no dyspnoea. Suddenly the patient complained of the onset of intense irritation round the body, and on exposing the skin I discovered a dense urticarial eruption chiefly on the flanks, extending down the thighs for about three inches below the groin. The limbs were otherwise clear. I now noticed that the patient's voice was becoming rather hoarse; the temperature was normal. The body was sponged with 1 in 100 carbolic lotion, which at once stopped the irritation and appeared to cool and calm the patient considerably.

The next morning when I called the patient was quite normal and clamouring to get up. The rash had quite disappeared, the voice was no longer hoarse, and the aeration of both lungs clear and good; with no adventitious sounds. I could discover very little which shed any light on the cause. Two hours previous to the attack she had taken a glass of milk which was rather sour. She had never before suffered from urticaria or asthma, and was perfectly well up to the moment of the attack.

Grays, Essex. F. E. WHEELER, M.R.C.S., L.R.C.P.

A CASE OF SPONTANEOUS RUPTURE OF THE UTERUS.

A MARRIED woman, aged 45, was admitted in labour to Queen Charlotte's Hospital on May 6th. The obstetric history was as follows:

The patient has had four previous pregnancies; the first and second labours were normal, the third was terminated by craniotomy because the child was stated to have been very large, and the fourth was induced at (?) thirty-two weeks, a live baby of 7 lb. being born. During the present pregnancy the presentation had been variable, occasionally a shoulder, but towards the end it was a vertex with no evidence of disproportion. It was thought wise to induce labour on May 10th, which was about her expected date. Labour started spontaneously on May 6th, and the patient was admitted at 3 p.m., after about twelve hours of feeble pains. The cervix was not fully taken up, the head was high and badly flexed, but could be pushed into the pelvis with difficulty. By 9 p.m. the head was well fixed, but the foetal heart could not be heard. The uterus was contracting feebly but regularly; the patient was tired, but in good condition. The os admitted three fingers. An old tear was noted on the left side, with one lip hanging down sufficiently to be mistaken at one time for a prolapsed cord. Morphine gr. 1/4 was given, and it was decided to do nothing further.

About 11.30 p.m. the patient began to complain of abdominal pain and look distressed, while there were no proper labour pains. The face became pale, and the pulse rose to 140. On examination the uterus could be felt contracting, while by the vagina there was no further advance. As it seemed certain the foetus was dead, the head was perforated without difficulty, but no attempt at extraction was made. During the night the pain continued, but the pulse fell to 110. By 9 a.m. on May 7th, however, it had risen again to 140. A further examination found the foetus easily palpable, and there was a firm mass on the right side; but per vaginam the head could not be reached, and the unoccupied cervix was hanging down into the vagina. It was now evident that the uterus had ruptured, and the patient was at once taken to the theatre and the abdomen opened. The foetus and placenta were found free among the intestines, together with much blood. The uterus was torn horizontally through the lower segment in front and to the left side. It was removed as rapidly as possible at the site of the tear, and after clearing out most of the blood the abdomen was sewn up without drainage. During the operation two pints of gum saline were injected intravenously. The patient's condition after the operation was good, and thereafter she made an uneventful and complete recovery. The temperature did not rise above 99.5° throughout the convalescence.

A piece of uterine wall at the edge of the rent was examined by Dr. Wilfred Newcomb at St. Mary's Hospital. He reported as follows: "The fragment consists of uterine wall with blood extravasated between the muscle bundles. In one place a small artery contains organizing blood clot and the muscle supplied by it is almost entirely replaced by oedematous fibrous tissue. It would appear that thrombosis of this vessel is the primary lesion causing partial infarction and fibrosis of a portion of the muscular wall which later ruptured."

The noteworthy points of this case are, first, the possible cause of the rupture as indicated by Dr. Newcomb, and its spontaneous occurrence after a short period of comparatively feeble pains. Secondly, the wide extent of the tear, which left only the posterior wall and right uterine artery intact. Should it be necessary to perform any internal manipulation for delivery in a similar case before rupture has been suspected complete avulsion of the uterus might easily be produced without any undue violence. The remarkably smooth convalescence was also unexpected.

My thanks are due to Mr. Aleck Bourne and Mr. L. C. Rivett for permission to publish this case.

London, N.W.1. I. H. K. STEVENS, M.D., M.R.C.P.

Reports of Societies.

RADIUM THERAPY.

Discussion by the Medical Society of London.

THE first discussion of the session in the Medical Society of London was held on October 28th, when the subject taken was radium therapy. Mr. DONALD ARMOUR, the president, was in the chair.

Mr. A. E. HAYWARD PINCH, medical superintendent of the Radium Institute, in opening, said that during the last twenty-one years he and his colleagues at the Institute had treated nearly 25,000 cases. He had seen the advent of radium therapy heralded with unreasoning enthusiasm as a panacea for all ills. These expectations were not realized, and then radium was derided; and afterwards ignored. Presently it became grudgingly accepted as a cure for some obscure and rare forms of disease after other treatments had failed to alleviate, but to-day it was universally recognized as a potent and in many respects unique addition to the surgeon's armamentarium. He deprecated the loose and indiscriminate use of the phrase "radium cure for cancer." The phrase was often extremely ill advised. He had recently seen some remarks in the lay press attributed to certain latter-day enthusiasts for radium therapy which he himself, from his special experience, would find the greatest difficulty in endorsing. Radium assisted surgery; but did not abolish it. Radium therapy meant a great deal more than the treatment of malignant disease by gamma radiation. He divided radium therapy into two parts: the first, superficial radium therapy, carried out with an apparatus unscreened or so lightly screened as to permit the passage of the beta radiation; the second, deep radium therapy, with apparatus screened so as to give entirely or almost entirely gamma radiation, with perhaps a minute proportion of beta. Superficial radium therapy, again, might be divided into the treatment of malignant and non-malignant conditions. This branch of radium therapy was extremely useful in the treatment of a variety of conditions, some of them not serious in themselves, but extremely annoying to their possessors. Pruritus was one example. Papillomata of the feet was another. At the Radium Institute, in the dancing season, quite a number of young people were treated for this condition. Another condition was acute papillomata of the ear, often so tender as to interfere with sleep at night; one treatment, and the thing was gone. Cases of lupus vulgaris occasionally came forward, having failed to respond to the usual routine treatments. In lupus erythematosus,

again, radium was used, not with the pretence of cure, but to secure a certain amount of comfort for the patient and to improve his appearance. Other conditions which responded to radium in a way which might be described as miraculous were very bad keloids, often developing in vaccination scars, also big diffuse cavernous naevi. As for malignant conditions, the chief of these for which superficial radium therapy was useful was rodent ulcer. He had noticed a striking diminution in the number of bad cases of rodent ulcer which had come forward during the last ten years, as compared with the number seen in the skin department when he was a student; this, he thought, was largely due to the application of radium, perhaps also x rays, in the early stages. Another amenable condition was mycosis fungoides, a disease the origin of which was unknown. He had a patient at the present moment who had had at different times thirty-five such growths excised from his body by surgeons. Epithelioma of the cornea, with an unscreened exposure of an hour's duration, could be successfully treated practically every time; and yet another condition in the same category was dermatitis pigmentosa. With regard to deep radium therapy the first of the non-malignant conditions where gamma radiation had had marvellous success in his hands was menopausal haemorrhage. He had had an unbroken sequence of 41 cases, all of which had been practically cured by radium treatment. At the same time, he had to admit the failure of radium in essential uterine haemorrhage in young women under 25. In cases of tuberculous adenitis, if in a fairly early stage, before suppuration, radium would certainly bring about absorption of the infected glands. In splenic leucocythemia, radium, while it would not cure, would help the patient very materially, and prolong life. It was of service also in lymphadenoma and lymphatic leukaemia. Coming, finally, to malignant disease treated with gamma radiation, Mr. Pinch put forward some hypothetical cases of cancer of the uterus and elsewhere, and discussed the prospects of surgery and of radiation. With regard to carcinomatous glands, whether secondary to cancer of the tongue or of the breast, he had tried all kinds of procedures, and frankly he did not know which was the best method of treatment. He had tried needling the glands, placing seeds in and around the glands, contact, crossfire, and focal radiation; the only thing he had not tried was bomb radiation, because the Radium Institute had not a bomb. In some cases he got a remarkable result, in others nothing whatever happened. He thought one of the biggest problems in radium therapy was the successful treatment of secondarily infected malignant glands. With regard to carcinoma of the oesophagus, he had treated some hundreds of cases, and had never cured one, nor seen a case cured. The best result he obtained was in one of his earliest cases, a man of 60, with almost complete stricture. After radium treatment he was able to eat mutton chops. But he died, unfortunately, twenty months later from lobar pneumonia. One of the great difficulties when a patient came up with cancer of the oesophagus was to determine the exact extent of the disease. In many textbooks a disease was alluded to as cardiospasm. His experience of cases with this denomination was that it was advisable to be on the look-out for the possibility of disease of the stomach wall at the cardiac end. Mr. Pinch added that, thanks to the foresight of the late Government, 20 grams of radium would shortly be at the disposal of the medical world. It was inevitable that some of this must fall into the hands of those who, to put it mildly, had not had any great clinical experience in radium therapy. He hoped they would not be too proud or too progressive to learn from the experience of their predecessors. The pathfinders in this subject had done much to clear out the jungle growth of ignorance and empiricism, but plenty of snags were still left for their followers to stumble over. At the Radium Institute any information desired would be placed at the disposal of medical men and physicists.

Professor Sidney Russ, director of the Physics Department, Middlesex Hospital, and scientific secretary of the Radium Commission, spoke on certain aspects of radium therapy which presented themselves to a physicist engaged on this work. The physicist tried to look at the thing quantitatively. It was usual to speak of the lethal action of radium. This did not mean that the radium rays cauterized the cells, but that they had some action on growing cells which prevented those cells from subsequent proliferation. By means of diagrammatic slides he endeavoured to get his audience to visualize the lethal action of a platinum tube of radium, anything from 1 to 6 cm. in length. The intensity of action fell off very rapidly with distance. From one table he showed it appeared that if the intensity at a certain short distance were taken as 100 per cent., it fell off to something like 4 per cent. at ten times that distance. But Professor Russ also pointed out how, judging from animal experiments, the action of a tube could be supplemented by tubes or other applicators placed in a different position so as to secure that a very large area received a more or less uniform radiation; it was a question of disposing or "staggering" the tubes. Incidentally he remarked that it was impossible to regard the Stockholm technique for the treatment of cancer of the cervix as able adequately to cope with extensions of the primary growth. One of the most interesting things arising out of the directly clinical application of radium in growths within the last five or six years had been a reduction of the intensity commonly employed in the tubes. Formerly it was quite common to have tubes of 10 or 20 mg. of radium element left in for twenty-four hours, and this, especially in certain sites, led to very unfortunate results. Good results had followed the introduction of radium of smaller intensity, from 0.5 to 1 mg., left in for seven or ten days. Especially in cancer of the tongue it had been found much better to lengthen the time of exposure and reduce the intensity of the dose. The reaction to radium was much more favourable with small intensities over a long time. Professor Russ proceeded to point out that in a tumour there were cells in every phase of division, some of them more susceptible to radium than others. Radiation, applied to groups of cells, prevented cells from reaching the stage of division, or daughter cells from maturing. He showed by diagrams how an application of radium in a rat had delayed the growth of the cells by as long as eighty days—a considerable fraction of the animal's life.

Mr. Duncan Fitzwilliams regarded the science of radium therapy as in no more than its experimental stage. In ten or twenty years' time he did not believe a single device employed to-day would be in existence. From the successes in radium treatment he learned singularly little; it was more intriguing to analyse the failures. He could talk with some authority about the entire failures he had seen with radon and radium. At present the work was being done largely in ignorance. No standards were available. The centres at Paris, Brussels, and Copenhagen all decried certain treatments, were perfectly stereotyped, and it was difficult to get them to do any experimental work outside their own accustomed field. In this country, until St. Bartholomew's took up the scientific investigation of the subject, radium was abused rather than used. The public had got the idea that it was only necessary to talk radium and the cure automatically followed. He feared, also, that in a few years' time there would be a number of commercial houses to which anybody could go and hire radon. The radon would be used by those who knew nothing about it, and in the most disastrous manner.

Dr. J. H. Douglas Webster agreed with the last speaker that in a very few years there was likely to be commercial exploitation of radon and radium. There was a good deal of this already in the United States, where it caused anxiety to the older radium workers. Dr. Webster showed photographs of some malignant cases, including squamous-celled carcinoma, which had remained well for five years. He doubted the statement that it was better to give doses of small intensity over a long period than to give large doses for a short period. He had found excellent results from using large intensities for a short time, and it was not yet determined whether the good results accruing under the other method might not be due to multiplicity of foci. He spoke also of the value of radium applied from a distance; he believed he was the first worker in this country to use it in that way. When radium was placed at a distance the possible damage to the skin was lessened. He endorsed what had been said

about the relatively little that was known on the subject of radium as compared with what in all probability would be known in thirty years' time. He believed that important arguments could be brought against any of the dogmas erected on the subject of radium. One method of treatment much spoken of was that of encircling the growth or the recurrence with radium tubes. But how could anybody be sure that the growth would extend in a circle? It might extend in an ellipse, or possibly have a ribbon development. A very good piece of advice was given by Mr. Fitzwilliams when he bade radium workers to study their failures. If the cases of failure were analysed the cause would nearly always be found to be wrong technique in the dosage. Either a sufficient total radiation was not given, or a sufficient amount was not given for the necessary length of time, or a sufficient extent was not treated.

Sir James Dundas-Grant said that one thing which had impressed him in the use of radon was the extraordinary relief afforded to people with cancer of the lower part of the oesophagus and the framework of the larynx. As a result of radon treatment these people had been able to swallow with great comfort until their death either from extension of the disease or from metastases. He mentioned the case of an old Chelsea pensioner who came with a tracheotomy tube, suffering great discomfort, almost unable to swallow or to make a sound. After the removal from the larynx of a considerable mass, three radon tubes were inserted into the base of the growth, and within a very few days the man took out his tracheotomy tube and found he could breathe without it. At the present time, a year afterwards, he was well, and nothing remained but the swelling of some epiglottic folds.

Mr. Arthur Edmunds, taking up a question put by Mr. Pinch as to what should be done in a case of commencing cancer of the tongue, with possible glandular spread, said that he would do as complete a dissection of the glands of the neck as he could straight away, and, at the same time, leaving some loose stitches in the middle, would insert radium, pushing the radium needle in from the base of the tongue. It was quite possible, having done an extensive dissection of all the glands of the neck, to put a finger in the mouth and get the radium quite low down at the level of the cricoid. Then, leaving the strings hanging out, one could complete the operation.

Mr. W. Gilliatt agreed that radium was a useful addition to the surgeon's armamentarium. This could not be overemphasized, at least in a gynaecological department. Since the beginning of 1923 he had treated all cases of carcinoma of the cervix at King's College Hospital, both operable and inoperable, with radium. The operable ones had been operated on subsequently to the radium treatment, and he could assure the society that the effect of the application of radium previous to operation had been beneficial in all but one case. He had done Wertheim's operation, following radium, on about forty-six cases. The striking features were the disappearance of growth of the hypertrophic type, the healing of the ulcerated type, and the possibility of doing the operation without the occurrence of post-operative sepsis. A very large number of patients upon whom Wertheim's operation was done died from sepsis as a result of the infection of the growth. His feeling with regard to the general results with radium was that there was some personal idiosyncrasy in the patient to account for the excellent reaction in some cases and the bad reaction in others when the conditions were practically of the same type and the technique was identical.

Dr. C. E. Lakin referred to the treatment of splenomedullary leukaemia. He had used radium rather than deep x rays because after surface application of radium he had rarely found any constitutional disturbance, whereas he could not say quite the same for x rays. Dr. Webster had been responsible for the radium treatment of the cases of spleno-medullary leukaemia in his wards, and quite a number had done remarkably well.

Mr. Hayward Pinch, in a brief reply, suggested that one meeting of the society each year should be devoted, not to a laudation of radium successes, but to a private confession of failures and mistakes. It would be an instructive, though probably not an overcrowded, meeting.

He fully agreed with Mr. Gilliatt as to the existence of some personal factor which, in an identical class of case, the same technique being used, led to remarkable differences in the result. He cited the case of two women, both of the same age, both at the menopause, who came to the London Radium Institute at the same time, and received the same treatment for a uterine condition. One of them was an inert, imperturbable woman, the other was highly strung and neurotic. In the case of the first the treatment was highly beneficial; in the case of the second it led to severe systemic disturbance and serious complaint from the lady's husband—a medical man—of the results of the treatment.

DISEASES OF THE PITUITARY BODY.

At a meeting of the Section of Medicine of the Royal Society of Medicine on October 22nd, with Dr. R. A. Young in the chair, Dr. W. J. Adie opened a discussion on diseases of the pituitary body.

Dr. Adie said that the tumour associated with acromegaly was usually a simple granular growth of the anterior lobe. There was a rough agreement between structure and symptoms, but no rigid formula was universally applicable. The commonest form of tumour in acromegaly might be very large and cause failure of vision, with granular symptoms absent or slight. A question which deserved consideration was whether an operation should be performed in the earliest stage of the disease in order to prevent abnormalities. Some day—probably soon—any ill effects which might follow the removal of the gland would be prevented by substitution-therapy; at present he did not think it justifiable to operate for such disturbances only. For every case which he encountered of pituitary tumour with acromegaly he saw five or six without it. The cardinal sign was loss of vision; there might be nothing else, but eyesight was often lost because these tumours were not diagnosed in time. In every case of failing vision without obvious cause, a pituitary causation should be suspected; indeed, he would go further, and search for a pituitary origin even when some other cause appeared to be at work. Toxic amblyopia was diagnosed too readily, and time was wasted while septic foci were being sought and removed. Congenital cystic tumours were unfavourable for operation, and the ultimate prognosis was bad. Dr. Adie then put a number of questions with regard to diabetes insipidus. Was this a symptom of uncomplicated pituitary disease, or was it always the result of damage to neighbouring nervous structures in the hypothalamus? Was it an expression of hyper- or of hypo-function of the control mechanism? Was it a simple symptom or a complex—the algebraic sum of disturbances of function? Did its clinical features vary with the site of the lesion producing them? Some of these questions had been answered; most of them were still open to discussion. To the first question the answer was definite: diabetes insipidus could result from a lesion confined to the pituitary body; it could also result from a lesion confined to the hypothalamus. How the mechanism acted, whether it was nervous or hormonal, was undetermined. But for many aspects of these questions regarding the elucidation of the symptom, special reference must be made to the clinician and biochemist, who must work hand-in-hand. From the findings of the biochemist and experimental physiologist a better understanding of the mode of production of diseases of the pituitary body would be reached.

Mr. Norman Dott mentioned briefly seven illustrative examples of these cases from the surgical point of view, and the variations in his treatment of them; he showed photographs and drawings of each. He referred to the purely hypothalamic lesions, cases in which there was impairment of vision alone, and other varieties. Recent evidence showed that eosinophil cells were concerned with growth, and basophil cells with sexual development and activity. The sexual functions might be depressed or not in acromegaly, presumably according to whether or not the basophil cell element was crowded out by the eosinophil hyperplasia.

Professor E. C. Dodds drew attention to various methods which could be applied to the investigation of pituitary

disease—methods which, he thought, had not yet come into the realm of ordinary routine examination in medical cases. It had been known for many years that the pituitary was associated with growth and with the control of the sexual function, but it was only in recent years that this had been demonstrated by animal experiments. There were to-day available very important methods of examination of the parts or secretions of the anterior lobe which were concerned with the regulation of sexual function. It had been possible to prepare, for example, from the anterior lobe of the pituitary an extract which, when injected into immature animals, such as young mice, would produce corpora lutea within fifty-six hours. It had been definitely shown that the anterior lobe produced a secretion which acted upon the ovary and caused it to produce in turn its own internal secretion, which would bring about the oestrous response in animals. If a young mouse was killed fifty-six hours after injection its ovary would be found studded with corpora lutea. Injected into the mature animal which was having its oestrous cycle, extract from the anterior lobe would first cause the animal to go into continuous oestrus, and then after a few days bring about the disappearance of the oestrus, which would be inhibited for as long as the giving of the extract was continued. The action was prolonged to such an extent that the ovary became exhausted, and could no longer produce its secretion, with the result that a condition of anoestrus was set up. This probably explained the occurrence of amenorrhoea in pituitary cases. All this, although it sounded so very speculative, had been found to hold good experimentally. Another very important fact, demonstrated recently, was that in the very early stages of pregnancy, possibly within the first few days, there was a certain discharge of this pituitary lobe hormone into the urine. That was interesting, and could be demonstrated by injecting the urine obtained from a pregnant woman into an immature female mouse. Within fifty-six hours the ovaries of the animal became covered with corpora haemorrhagica. This definite means of diagnosing pregnancy had been used in Germany a good deal and in this country to some extent. If the anterior pituitary lobe was transplanted into immature male animals the development of puberty was brought about, with dropped testicle and the appearance of spermatozoa. He thought that if cases of this nature were examined by this technique of injecting into immature mice either the urine or extracts from the blood, a good deal of information as to the internal secretory nature of the tumours might be elicited. The methods were very simple for anyone who had at his disposal an animal house. It would also be interesting to try these anterior lobe extracts on cases where there appeared to be hypofunction of the gland.

Dr. O. Leyton confined himself to some observations on the relative effects of different preparations on the market. Some years ago, in treating a series of cases of diabetes insipidus, he found that certain extracts on the market had very different effects from others, some controlling the diuresis very well, others doing so only to a slight degree, although all were standardized preparations. This led to the belief that the oxytocic material and that which controlled diuresis must be different. The experiment had for its object the determination whether vasopressin was the antidiuretic substance. He recounted the experiment and named the preparations used. The experiment showed that the two substances were not identical.

Dr. Macdonald Critchley spoke of epithelial tumours occurring in the pituitary and superpituitary bodies. He instanced in the first place cysts of Rathke's pouch, which were rather rare tumours; then simple papillary cysts, which were also rather uncommon; adamantinomata, which were the most characteristic tumours in this situation, characterized by a single peripheral layer of columnar cells; and, finally, spindle-celled carcinoma, which was excessively rare. It was also just possible that there was another type of embryonic tumour growing in relation with the pituitary body and perhaps arising from the infundibular recess. He exhibited photomicrographs of all these varieties.

Mr. H. W. B. Cairns referred to the differential diagnosis of hypophyseal lesions from the surgical point of view. He dealt upon the importance to the surgeon of an accurate diagnosis of diseases of this group. Occasionally acromegalic patients might be found to have a normal sella turcica. He thought it within the bounds of possibility that operation might come to be undertaken for the relief of acromegaly pure and simple. Dealing with cysts of Rathke's pouch, he said that this condition was sometimes confused with tumours of the third and fourth ventricles, but gliomas of the third ventricle could be distinguished as a rule from pituitary tumours.

Dr. F. A. Pickwell, dealing with pituitary infection by contiguity, pointed out that the sphenoidal sinus had only a very small communication with the nasopharynx, and that pus within the sinus escaped only with difficulty. There was thus a tendency for toxic products to be absorbed locally, and it was obvious that the pituitary body, which in this case was practically suspended in a bath of pus, must be seriously involved. It had been possible to demonstrate histologically a few organisms within the gland, which was seen to contain some large masses of colloid. Resistance to the spread of organisms had been shown to depend, first, upon the sinus membrane, and secondly upon the dural capsule of the gland, the intervening bone offering much less resistance. He and those associated with him at the Joint Board of Research for Mental Diseases at Birmingham were of the opinion that large masses of colloid were in many if not most cases due to bacterial toxin acting on the pituitary substance, and, conversely, they were placing some relative importance on the presence of large masses of colloid as at least some indication of previous sepsis in or adjacent to the gland. He went on to argue that there existed an explanation of the varied symptoms ascribed to the pituitary in the extension of sepsis by contiguity from the sphenoidal sinus to the pituitary and hypothalamus. A sphenoidal sinusitis might resolve or become chronic and involve bone. If the roof of the sinus was affected, or if the sinus became filled with septic secretion, the pituitary would be involved, producing varied endocrine symptoms in accordance with the age and stability of the other endocrine glands of the body. Should the septic absorption or pressure of invasion proceed further, there resulted disturbances of metabolism such as diabetes, dystrophia-adiposo-genitalis, and cachexia. By still further spread it was postulated that the nuclei surrounding the third ventricle was affected, resulting in clinical symptoms of lethargy, katatonia, and irritability, which might progress to a condition recognized as mental disorder.

Dr. T. C. Graves said that the occurrence of endocrine disturbances in these patients was now generally accepted, but such disturbances were extremely variable and were so overshadowed by mental symptoms that they might not be adequately recognized. Especially was this the case in reference to the pituitary, since the symptoms of disorder were indefinite, and varied with the view taken as to the extent of the inclusion of disturbances of function of adjacent nervous tissue. There were, however, some symptoms of frequent occurrence in the subjects of mental disorder which appeared to him to have a direct relation to pituitary function. These were: general loss of muscle tone; disturbances of the peripheral circulation causing extreme facial pallor and cyanosis of the dependent parts; disturbances of nutrition, with extreme emaciation, which might be followed by obesity; and, finally, disturbances of the reproductive mechanism—for example, amenorrhoea. He showed a large number of photographs illustrating particular cases, and also indicating the recovery of patients under treatment.

Dr. Bernard Myers commented upon the absence of any mention of blood pressure. As a clinician he would suggest that blood pressure was distinctly of some importance in these cases. In his experience he had a case of pituitary adiposity in a girl aged 11, with low blood pressure. The effect of giving pituitary by the mouth was to drive the systolic pressure up to 150, and it dropped to 105 when the pituitary was discontinued.

Dr. Adie, in a brief reply, mentioned that he had noticed in a recent German publication the statement that the pituitrin manufactured by a certain British chemical house was still the best of all the products available.

Reviews.

MARTINDALE'S EXTRA PHARMACOPOEIA.

The second volume of the nineteenth edition of the *Extra Pharmacopoeia of Martindale and Westcott*,[1] which has just appeared, well maintains the reputation of this work. As most of our readers will be aware, the volume consists of a collection of data concerning the numerous sciences on which therapeutics is based. It covers a wide range of rapidly expanding sciences, and with each successive edition the task of keeping the contents up to date must become more difficult. The author, Dr. W. H. Martindale, is to be congratulated on the untiring energy and industry he has expended on this work for so many years. He has ransacked the literature with remarkable thoroughness, and has collected information concerning the most recent advances. He has even succeeded in introducing into the index references to articles that have appeared within the last month. The greater portion of the volume is devoted to pharmaceutical chemistry, analytical chemistry, biochemistry, pharmacology, and bacteriology, and these subjects are dealt with in a very satisfactory manner. There is also a section of 50 pages on radiology, ultra-violet light, and radium. These are subjects that are developing particularly rapidly, and no fewer than 160 new references have been introduced into this section.

A special feature of the book is the amount of space devoted to matters affecting the public health. In the first place the volume forms a valuable legal reference book, for summaries are given of the enactments that control the sale of foods and drugs. Much of this legislation is too recent to be noted in most standard textbooks, and hence the volume is specially useful in this respect. It also provides information concerning other subjects controlled by official or semi-official pronouncements, which are of importance in public health and therapeutics, but which are not the immediate concern of any particular science, and hence are peculiarly difficult to locate in works of reference. For example, the volume gives information about the following subjects: the methods for biological standardization of drugs, with reference to the official or semi-official announcements on this subject; the findings of inquiries regarding the toxicity of tetra-ethyl lead; evidence regarding the iodine content of British waters and the use of iodized salts in the prevention of goitre; and the conclusions of official inquiries made regarding the bleaching of flour. The few examples we have picked out for mention are sufficient to show the remarkable variety of the information that the author has collected into a single volume.

This book has a well-established reputation as a most useful and convenient work of reference for medical men, and the present edition will add to its popularity.

A HISTORY OF BIOLOGY.

In Erik Nordenskiöld's *History of Biology*,[2] which has been well translated by Mr. L. Bucknall Eyre, we have an excellent survey of the development of that science, viewed in relation with the general cultural development of mankind. Treatment of the subject on these lines is of special value to the biologist and to the general reader, since it is the only means by which a clear vision of the present position of biological science can be obtained.

As is well known, biology had its origin in the philosophical systems of the Greeks, and at first it had no separate existence apart from general philosophy. At the present time it may be defined as the science of the phenomena of living matter. The delimitation of its scope was a gradual process, which is well portrayed by the author in a series of biographies of men representative of the ideas of their period; these, varying in fullness of detail according to their importance, are interwoven in the narrative and form a very valuable feature of the work. Closely associated with the evolution of ideas and theories has been the gradual accumulation of material facts, the rate of progress of which has depended on political and social circumstances and on the introduction of new methods of research. The author discusses this parallel development in relation to every branch of biological science. Observation and hypothesis, which with experiment form the tripod of modern scientific method, were first practised by the Greeks, who, according to the author, derived their freedom of thought from the particular character of their political system. Unlike the primitive races, their organization left them free to investigate nature with the direct object of finding an explanation of existence, and not merely to help them in the art of placating gods and demons; and their science progressed steadily up to the time of their absorption into the Roman Empire. Their store of facts was, however, necessarily scanty, and their biological systems were, therefore, largely theoretical; and as they had but an imperfect idea of the distinction between fact and theory, their systems were essentially dogmatic. Their most highly elaborated system, that of Aristotle, postulated a divine guiding intelligence rendering every phenomenon of existence purposeful, with a striving towards ever higher forms. Form was held to be the only reality, perfect in the divine intelligence, non-existent in formless matter—which was regarded as potentiality without reality—imperfect, but tending towards perfection, in the terrestrial sphere, within which it exhibited varying degrees of dominance over matter, slight in inanimate objects, more potent in the animal and vegetable kingdoms, and highest in human consciousness and reason. This was a complete theory of evolution well calculated to promote the progress of biological science had not circumstances, political and ecclesiastical, brought about its undoing.

Amid the general Roman degradation science died out, but fortunately the Greek philosophy found a home in the outskirts of the Empire—in Persia, Syria, and among the Arabians—and it gradually filtered back to Europe, enriched by the Arabian discovery of the experimental method, at a time when the Catholic Church had become the dominant cultural centre. The Aristotelian system, with its postulate of a divine guiding intelligence, proved compatible with Catholic doctrine; it was adopted by the Church and acquired almost the character of an accessory creed, which, though it was necessarily erroneous in innumerable details, it was deemed heretical to question. Catch-phrases and appeal to ecclesiastical authority took the place of the observation of nature, and freedom of thought was curbed by the strong hand of the Church. Wielded by a few independent thinkers, the experimental method—the *novum organum*, to use Bacon's expression—in which the appeal was directly to nature, was instrumental in liberating science from ecclesiastical authority. "Facts wait not on opinions," wrote Harvey. "The things of nature bow not to antiquity. There is nothing more ancient or of higher honour than nature." Questions posed for nature to answer under controlled experimental conditions replaced the appeal to authority and dogma in scientific questions, and in the hands of such men as Galileo and Harvey results were immediate. Science made a fresh start, discoveries of great importance were recorded, and the subsequent progress of biological science, as of science generally, has been uninterrupted and phenomenally rapid. Nordenskiöld closes the first section of his history at this point; in the second section, covered roughly by the seventeenth and eighteenth centuries, he describes the elaboration of new biological systems to fill the void left by the breakdown of scholasticism. Among the numerous theories which were the product of the time the mechanistic theory of Descartes and the animistic theory of Stahl serve to illustrate the main lines along which biological thought was moving—on the one hand towards materialism and a purely mechanical view of life, on the other towards a mystical interpretation of nature. Descartes, rejecting the theory of final causes, held that the body was best regarded simply as a machine, every phenomenon of which was to be explained on mathematical principles. The theory was of value in giving an impetus to research into

[1] *The Extra Pharmacopoeia of Martindale and Westcott.* Revised by W. Harrison Martindale, Ph.D., Ph.Ch., F.C.S. Nineteenth edition. In two volumes. Vol. II. London: H. K. Lewis and Co., Ltd. 1929. (Fcap. 8vo, pp. xxxviii + 752. 22s. 6d. net.)

[2] *The History of Biology.* By Erik Nordenskiöld. Translated from the Swedish by Leonard Bucknall Eyre. London: Kegan Paul, Trench, Trübner and Co., Ltd. 1929. (9 × 6, pp. x + 623 + xv; illustrated. 30s. net.)

the purely mechanical and physical processes of the organism; but in claiming to explain the more complex vital phenomena it was in error and tended to materialism. Stahl's theory postulated the existence of a soul, independent of the body, but inducing and controlling all its actions, which he supposed were undertaken exclusively for the sake of the soul. The futility of metaphysical theories of this type, which by a confusion of fact and theory offered a ready explanation for any and every problem, has been better appreciated since Kant (1724) defined the two kinds of reality with which the mind has to deal. He distinguished between realities the knowledge of which we gain through the evidence of the senses, and realities about which such knowledge gives no information, the latter falling outside the sphere of rational knowledge, although legitimately and usefully pictured according to individual fancy.

Of greater interest than these speculations was the solid work done during the period in the systematic description and classification of living forms by Ray, Linnaeus, Buffon, Lamarck, Cuvier, and others. These studies revealed the fact that no clear line of demarcation could be drawn between animal species; that it seemed possible to arrange animal forms in a single linear series (Bonnet, Lamarck), or in several parallel or branching series of gradually increasing complexity (Cuvier). It was but a short step to the conception that similarity of form might indicate genetic relationship, higher forms being evolved from lower. The theory of evolution was thus reintroduced into biological science. It made no headway at the time, however, owing, as the author considers, to the prevailing tendency to philosophize on the development of life in nature, a tendency which lacked all feeling for material development. Lamarck's theory of evolution, for example, was merely an incident in his somewhat fantastic speculations upon life. The account of the definite establishment of the theory of evolution forms the central matter of the third and final section of Nordenskiöld's work. Darwin, with an initial prejudice in favour of the fixity of species, approached the question as a specific problem apart from philosophical speculation; he adduced good evidence for believing that species were mutable, and thus placed the theory of evolution on a sound basis. The general acceptance of the theory was, in Nordenskiöld's opinion, greatly favoured by the liberalism of the nineteenth century with its pronounced faith in progress, but it was through Darwin that evolution was elevated to a natural law governing all life. His theory was hailed with enthusiasm by all who cherished the ideals of the new age; it has taken the place of idealistic theories and made common descent the connecting link in existence instead of ideas and archetypes, and in every sphere of knowledge the development from earlier to later stages has now become the one clue to research. As regards the present, modern research in heredity has introduced a different and essentially experimental treatment of the problem of evolution, and the old morphological speculation upon the origin of species, with its undue insistence on external causes in explanation of the phenomena of life, has lost ground. It has come to be recognized that evolution is a part of life itself.

GONOCOCCAL ARTHRITIS OF THE HIP.

Considerable attention has of late been paid, especially in France, to the study of what used to be called gonorrhoeal rheumatism, the more acute forms of which are very grave and extremely painful affections, leading, in the case of the hip, too often to pathological dislocation. This disease was first described by Coulson of London in 1837. The general subject was very fully and ably discussed from the surgical point of view last year by Dr. H. Mondor in *Les Arthrites gonococciques*, of which a review appeared in our issue of January 12th, 1929 (*p. 70*). The more restricted field of such affections localized in the hip-joint is now presented to us by Dr. Marthe Lamy in a monograph entitled *La Coxite gonococcique*,[2] based on the study of 130 cases already published, to which are added eleven cases collected by the author, who seems justified in stating that this localization is much less rare than had been thought by such authorities as König of Berlin. It occurs in both sexes, but more often in the female (nine out of eleven of the author's cases), especially if one admits that many cases of puerperal arthritis are of gonococcal origin. Gonococcal joint disease in infants is as yet not well known, but the author cites B. Cooperman (*American Journal of Diseases of Children*, February, 1926, p. 183) as an authority who has shown how disastrous to the joint such lesions can be. One of the most characteristic symptoms of acute gonococcal arthritis is the intensity of the pain.

The author holds it as certain that the disease is essentially an osteo-arthritis, and that this early affection of the bone accounts for the alterations in the acetabulum and femoral head which permit of luxation. In six out of the eleven cases referred to such a luxation occurred, and the author considers it as inevitable in severe adult cases, as well as in young infants, on account of the early disappearance of the capitular epiphysis. Dr. Lamy asks the question, suggested by radiographic appearances, whether the gonococcus may not be the cause of some so-called congenital dislocations, of coxa vara, and Legg-Calvé disease as well as of arthritis deformans and morbus coxae senilis. This question cannot be answered in the affirmative until a great deal of evidence has been brought forward, which is at present non-existent. The seventeen cases followed up by the author yield the following statistics: One death from secondary septicaemia. Eleven pathological dislocations with serious shortening, up to 4 centimetres. Only three of these cases healed without ankylosis. Three others are contracted in flexion. Apart from serum and vaccine treatment, according to our author, the only means of actively combating the consequences of the destruction caused by the infection is continued extension, associated or not with immobilization in plaster-of-Paris. It is worthy of a note that in one case when the last-named means had entirely failed to relieve the excruciating pain and spasm, weight extension was at once successful, as it has so often proved to be in acute tuberculous coxitis.

The number of detailed case reports and the illustrations add to the interest of this book, which offers, together with that of Mondor, an excellent survey of the subject of gonococcal arthritis.

THE LITERATURE OF OTOSCLEROSIS.

The publication of two volumes on otosclerosis[1] is part of the investigation of this disease, well described as the bugbear of otology, which has been undertaken by a committee of the American Otological Society at the instigation of Dr. Arthur B. Duel since 1924. These volumes, each divided into two sections, contain abstracts of everything that has been reported in medical literature on the subject from 1735, when Valsalva described ankylosis of the stapes, down to 1928. In the first volume pathology is examined under the headings of stapes ankylosis and changes in the labyrinthine capsule, and etiology under the headings of heredity, congenital conditions in the labyrinthine capsule, local conditions, and general conditions. The second volume is devoted to symptoms and diagnosis, and lastly to treatment, including local surgical measures, local non-operative measures, and general treatment. There is, of course, an exhaustive bibliography, and it would be a keen eye that discovered any omission. This gives a general idea of the methodical way in which the work has been attacked and carried through. There is neither comment nor criticism, only a record of all that has been done and written, and the industry devoted to it must evoke our respectful admiration.

The material difficulties have been smoothed by the grant of a large sum from the Carnegie Corporation, but money alone could play only a small part in the production of a work so perfectly designed and executed. It will naturally make no appeal to the general medical reader, nor even to the average otologist, but equally it will remain for all time essential to anyone who undertakes or even

[2] *La Coxite gonococcique.* Par Marthe Lamy. Paris: Gauthier-Villars et Cie. 1929. (6 × 9¼, pp. 259; 31 figures. 35 fr.)

[1] *Otosclerosis: A Résumé of the Literature to July, 1928.* Compiled under the direction of the Committee on Otosclerosis, American Otological Society. Vols. I and II. New York: P. B. Hoeber, Inc. 1929. (6¼ × 9¼, pp. vii + 409 + xxii. 35 dollars the two volumes.)

contemplates any research work in the pathology of the temporal bone. It will give to many an ardent spirit good reason to pause and consider when he finds that his original ideas have already been fully exploited, and will save many from disappointment and repetition. This work is the preliminary to an intensive investigation of otosclerosis, but by itself it places the science of otology under a heavy debt to Dr. Duel and those whom he has inspired.

PRIMERS FOR DIABETIC PATIENTS.

Dr. Rudy's *Practical Handbook for Diabetic Patients*[5] is a volume designed for the use of the diabetic aliens and Jews among American immigrants. It gives a clear account, adapted to the needs of the layman, of diabetes and insulin treatment; and this is followed by food diagrams and charts and suggestions for diets that are of great practical utility. Some 200 recipes for the kitchen are added, taken from the menus of many nationalities, so that Jews, Greeks, Armenians, Swedes, Italians, and the French are catered for in Dr. Rudy's book. It is clearly written, and the so-called "substitution charts" constructed by the author enable those who use them to make many variations in what is often a monotonous diet, without going beyond the physician's prescription. The volume is undoubtedly useful, and may be recommended to the attention of diabetic subjects.

Dr. Cammidge's *A Dict Summary in Average Servings for Diabetics*[6] is a pamphlet setting out a system for the quantitative regulation of the diabetic diet, with or without the use of insulin as well. It is full of concentrated information, and should be of service as a *multum in parvo* to diabetic patients anxious to construct safe and satisfactory diets for themselves.

Similar in aim and equally successful is *The Diabetic A B C*[7] by Dr. R. D. Lawrence, a practical book for patients, particularly those using the line-ration diet, which the author has fully described in *The Diabetic Life*. In a small compass the volume includes an account of what diabetes is and how it is treated, and advice to the patient on the routine he should adopt in order to remain well and the precautions he must take when he is ill. To the description of the line-diet system the author adds a number of useful recipes prepared by Staff Nurse Wheeler, of the diabetic kitchen at King's College Hospital.

NOTES ON BOOKS.

Drs. Donald Paterson and J. Forest Smith, in revising their work entitled *Modern Methods of Feeding in Infancy and Childhood*,[8] of which the first edition was reviewed in our columns on July 17th, 1926 (p. 118), have increased its usefulness by adding a chapter on diets for sick children and children of school age, a section on stools in infancy, and a description of common articles of diet, with their uses and digestibility. They have rewritten the sections on vitamins, condensed milks, and artificial foods, and the instructions for preparing lactic acid feeds. The general practitioner confronted with feeding problems will find in this work the practical information he requires presented in a clear and dogmatic manner.

A second edition of *Practical Clinical Psychiatry*[9] by Drs. Edward A. Strecker and Franklin G. Ebaugh, has recently been published. We commented favourably upon the first edition (April 10th, 1926, p. 660), and it is evident that it has met the needs of the student and young psychiatrist. Additions have been made to several chapters, and short sections on the management of post-encephalitic behaviour disturbances, physical habitus and mental disease, and the newer treatment of general paralysis are now part of this volume. The author has also felt it desirable to write a chapter which attempts to delineate the elements of psychological conceptions of mental disease.

An unusually rich store of information for all interested in the territories covered—as business men, as settlers, as tourists in search of health, sport, or the simple attractions of travel—is provided in the *South and East African Year Book and Guide for 1929*.[10] Issued under the auspices of the Union-Castle Mail Steamship Company, it contains, in addition to the usual topographical and travel guide-book matter, special sections dealing with climate, public health, immigration, industry, agriculture, game hunting, and fishing. An account of Mauritius is included. There is also a useful gazetteer, and an extensive atlas with excellently printed maps. The price is low, considering the size and quality of the volume.

In a small pamphlet on the nature and pathogeny of cancers[11] Dr. E. Georgiou, after a long theoretical dissertation, mentions a series of experiments in the following terms: "Sixty mice were employed in the experiments, forty-eight of which had spontaneous malignant growths of the breast or skin. The animals were divided into four groups of twelve each, the ages ranging from 10 to 20 months. In the first set the pineal gland was excised and a graft of the sexual gland implanted. In the second group excision of the pineal gland alone was performed. In the third group a sexual graft alone was employed. The fourth group served as control. The animals of the first group which survived the operation (seven out of twelve) were cured of their cancers and showed signs of rejuvenescence. The surviving half of the second group were radically cured of cancer, but showed no rejuvenescence. The third group exhibited no improvement as regards the cancers, and the sexual grafts failed to take." These experiments cannot be regarded as of much interest in the absence of complete protocols.

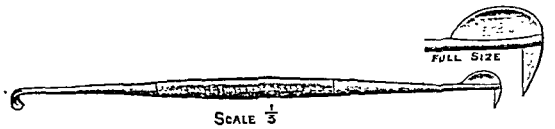
PREPARATIONS AND APPLIANCES.

A Tonsil Enucleator and Pillar Retractor.

Mr. W. S. Thacker Neville, M.D., F.R.C.S.Ed. (Harrogate), writes: The late Mr. Syme of Glasgow kindly demonstrated his quick dissection operation to me several years ago. He performed the operation under ethyl chloride. He made an incision round the tonsil and then swept down behind the tonsil. For both these movements he employed one instrument, and then he completed the removal of the tonsil by means of a wire snare. This procedure of Mr. Syme's is an ideal operation, but



Scale ½

it requires great dexterity and quickness if done with ethyl chloride anaesthesia, and so I have combined three instruments into one in order to do the operation quickly. The pointed knife makes an incision round the tonsil, the oval knife on the opposite side separates the tonsil from the fossae, an Eve's snare is then applied and screwed up and left on the tonsil. The other tonsil is then similarly treated, and finally both tonsils are removed. The pillar retractor allows one to depress the tongue and inspect the fossae. This instrument is made by Thackray of Leeds.

An Adhesive Dressing.

Elastoplast is described as a surgical dressing, made of material which has been specially woven to give the maximum stretch cross-wise, and covered with an elastic antiseptic adhesive plaster. The manufacturers claim that it is firmly adhesive, provides an even support, and, as it need not be removed when taking a bath, it may, if necessary, be left *in situ* for weeks at a time. A cabinet, fitted with a useful range of elastoplast dressings, has been prepared for the medical profession, and may be recommended to the notice of busy practitioners who would prefer, in treating minor injuries, to apply dressings that will remain in position without bandaging. Particulars and prices may be obtained on application to Messrs. T. J. Smith and Nephew, Ltd., Neptune Street, Hull.

Nova et Vetera.

FIELD ARCHAEOLOGY.

A Book on Prehistoric Sussex.

The two Dr. Curwens of Hove—*fils et aîné*—have long been known to archaeologists for their magnificent field work. *Prehistoric Sussex*,[1] by Dr. E. Cecil Curwen, comes, therefore, from no superficial week-ender. For seventeen years he has studied his ground. Every break in the rounded outline of the hills he has realized as due to the hand of man, and has set himself to solve its purpose. He has called in the aid of photography, both surface and aerial; he has measured, surveyed, and excavated; and he has checked his conclusions with a sound knowledge of museum archaeology, and of the work of other archaeologists, in which Sussex has been particularly rich. The result is a book—sound, safe, and clearly written—which will serve as an introduction to the whole subject of field archaeology, as well as to the special study of the Southdown Ridge.

There are chapters on flint mines, burial mounds, hill forts, villages and cultivation, prehistoric and Roman roads, miscellaneous earthworks, and on their detection and mapping; and each chapter is followed by a valuable list of localities and full bibliographical references.

Flint, to be easily worked, must be unweathered and fresh from the chalk. It was obtained by sinking groups of shafts from ten to fifty feet deep and extending galleries as much as fifty feet long. As each shaft was exhausted it was filled up with the spoil of the next one dug, and excavation often reveals a network of communicating galleries with the deer-horn picks and even the smoke stains from the miners' lamps of nearly four thousand years ago. For the late Neolithic age of these mines is proved by that of the fragments of pottery, and the forms of the flint artefacts worked and left *in situ*. With the exception of Grimes's graves in Norfolk, all that have been excavated in England are found in Sussex.

Sepulchral tumuli, single and in groups, which are found along the ridgeways are of all periods, from the Neolithic long barrows which occur in two localities—one at each end of the county—to the various round forms of later date; and the author has an interesting digression on Mr. Hadrian Allcroft's theory of the derivation of the Christian "church," in both etymology and origin, from the sacred circular mound.

Of the twenty-three "Hill Forts" which occur under this heading, only three or four belong to the Early Iron Age class of strong camps more common in the Wessex country. But if Sussex is not rich in these, she can boast of no fewer than three out of the five examples so far recognized in England (and two of the three have been proved by excavation) as belonging to the Neolithic Age. Dr. Curwen's survey and excavations at the Trundle overlooking Goodwood racecourse, where the trace of the older earthwork inside the well-known hill-top fortress was revealed by air photography, is an outstanding piece of work.

The Southdowns are rich in traces of the early "Celtic" square-field cultivation, and if the villages are not so numerous as they are in Wiltshire, the description of the settlement excavated at Park Brow, near Worthing, with its three successive occupations of Late Bronze, Early Iron, and Romano-British date, each with its own peculiar form of dwelling, is one of the most interesting in the book.

The roads and trackways—early British and Romanized—and the well-known military Stane Street are all admirably dealt with, while the chapter on miscellaneous earthworks gives a description of archaeological puzzles which await solution. There are descriptions of special localities rich in such features; in one, Bow Hill, near Chichester, there are no fewer than sixteen objects of archaeological interest within the compass of a day's walk. Dr. Curwen's section on the diagnosis and detection by percussion of ploughed-out earthworks will interest his medical colleagues. His percussor is a navvy's rammer, and the relative resonance of "thud" and "thoomp" distinguish between wasted bank and filled-up ditch. But the whole book is admirable, and, dealing with a country so well known and accessible, it will do much to advance not only interest in, but the real scientific knowledge of, field archaeology.

J. P. W.-F.

[1] *Prehistoric Sussex*. By E. Cecil Curwen, M.B., B.Ch., F.S.A. With a foreword by O. G. S. Crawford, F.S.A. London: The Homeland Association, Ltd. 1929. (Demy 8vo, pp. xi + 172; illustrated. 10s. 6d. net.)

AN EARLY ADVOCATE OF EXERCISE IN THE OPEN AIR.

One of our readers has turned up among some old family documents a MS. copy of the set of verses printed below. The paper on which they are written bears the watermark "R. Tassell, 1834," and the inscription on the wrapper suggests that they were copied from some local newspaper by one lady for the entertainment of a friend. At the foot of the poem appear the words, "Inscribed very mirthfully to Dr. Jephson." We have not been able to identify Dr. Jephson of Leamington, but he evidently preached the gospel of fresh air and exercise at a time when such views found little favour with his colleagues.

Leamington Peripateticks,
or
Use your Limbs and Have Them.

Scene.—*Union Parade, a Stranger meeting a Patient of Dr. J---n's.*

Stranger: I hear Sir yr Warwickshire far-famed Physician
Who seems to cure all whate'er their condition
Has revived the old school of Athenian ethics,
Or at least the old name of the Peripateticks.
Pray is it not true, with child, woman and man,
He makes walking a *sine qua non* in his plan?

Patient: He does Sir; So much so that some have a notion
The secret is his of perpetual motion,
For all the disciples who bow to his sway
Walk out at all seasons all hours of the day!
They walk when the north wind blows piercing and bleak,
They walk when their mouths are so stiff they can't speak;
They walk in the mists and cold fogs of *November*,
They walk in the drizzle and damp of December.
They walk when it thaws, they walk when *it freezes*,
They walk for all causes to cure all diseases.
They walk when they have not a limb that is sound,
They walk when they cannot set foot to the ground.
They walk when their poor backs are ready to break,
They walk though each bone in their bodies may ache.
They walk when they're fasting, they walk when they've eaten,
They walk when so weary, they had rather be beaten.
They walk when *they're peevish, they walk when they're placid*,
They walk when they're pinched with the Sulphuric acid.
They walk after faintings, hysterics and fits,
They walk in their senses and out of their wits,
They walk if they're commoners, walk if they're peers,
They walk if they're young, middle aged, or *in years*.
Epileptic, Dyspeptic, Rheumatic, what not!
No matter what ails them, they set off full trot!
Be they gentle or simple, Plebeian or noble,
All walk, or if gouty, at least they all hobble,
The Plethora walk, in the hope to grow paler,
The palid ones walk to grow stronger and haler,
The stout and unwieldy they're walking for that,
The bony and skinny they walk to grow fat,
If some walk too slowly they're joined by "the Master,"
Then surprising to see they walk faster and faster.
At other times body and soul make resistance,
But with him they can walk, any pace, any distance.
In short he makes those walk who ne'er walked before,
And those who have always walked here walk still more.
'Tis rumour'd Jephsonian trained Infants are able,
To walk the first month, but this must be a fable,
But who knows what strange marvels may meet our inspection
When walking like steam shall be brought to perfection.
Which it must be in Leamington where without strife
Walking forms the chief end, the main business of life.

British Medical Journal.

SATURDAY, NOVEMBER 2ND, 1929.

THE PANEL CONFERENCE.

DURING the last year or two the matters dealt with at the Annual Conferences of representatives of Local Medical and Panel Committees have not been of such fundamental importance, and hence have not afforded evidence of so much controversial feeling, as was the case in some former years. The two main subjects discussed at the Conference held last week are, however, of great general interest to the medical profession, and do not merely concern those who are engaged or interested in insurance practice. These subjects were medical certification, and the availability of hospital practice and experience for general practitioners.

Great importance in many spheres attaches to correct and judicious medical certification. This has been impressed upon the profession many times by precept, by warning notice, even by penal example. Under the national health insurance scheme the extent of medical certification is so wide, and its effect on the success of the system and the financial stability of many approved societies is so vital, that some rules have had to be made with regard to the forms and methods of issue of the more usual certificates. One or two of these rules might well be modified, and it is probable that the approved societies have been unwise, even in their own interests, in resisting certain proposals for such modification which have from time to time been made by the Insurance Acts Committee. The part which alleged improper certification has played in relation to the greatly increased claims for sickness benefit during recent years has been much exaggerated, and extravagant statements on this matter are still occasionally made by some members of Parliament and society officials. Though it is now generally admitted that the increase in sickness claims has resulted from many other causes, some of them still quite mysterious, yet it remains true that the demand for the greatest care in medical certification is a perfectly legitimate one. Such certification may be imperfect in three directions. It may be deliberately or stupidly false. If a medical practitioner puts his signature to a statement which he knows to be untrue (even if he is pleased to consider it unimportant) this constitutes a very grave professional offence, and will probably be dealt with severely by the General Medical Council. Again, a certificate may be not false, but irregular—that is, not in accordance with the rules laid down. The giving of such a certificate must be recognized as a definite offence, even though it is often committed in response to a patient's appeal, and even sometimes at the direct instigation of the agent of an approved society. The machinery and procedure for dealing with such irregularities are laid down in the Medical Benefit Regulations, though an approved society, before setting such machinery in motion, might often be wise to consider whether a letter of inquiry, or a reminder to the doctor of the rules, would not be sufficient to meet the case. Further, a medical certificate, without being either false or irregular in the sense above indicated, may still be lax in so far as sufficient thought and care have not been exercised, or in so far as wrong or irrelevant criteria have been applied in arriving at a decision. Such laxity may have serious consequences, but as yet no method has been adopted for dealing with it.

The devising of some such method is the problem with which the Insurance Acts Committee and the Panel Conference were concerned. Certain proposals were made in the report of the Committee which have received the provisional approval of the Ministry of Health, though not yet that of the Scottish Board of Health. These proposals were endorsed by the Conference. Clearly this laxity of certification is, in the main, a matter of professional judgement, and the proposals for meeting it are therefore properly based on the principle that the investigation of any allegation of this kind of laxity should be conducted, and conclusions formulated, by purely professional tribunals; though provision is made that, when the conclusions have been arrived at, the advice of approved societies and of Insurance Committees may be sought before any decision as to penalty is promulgated by the Minister. The maintenance of this principle is of importance to the whole profession, and it is to be hoped that, however much the details may be modified in further pending negotiations, there will be no departure from it.

The second main subject of discussion at last week's Panel Conference eventuated in the passing of the following resolution: "That it is desirable that provision be made in, or in association with, voluntary hospitals and municipal hospitals, or in separate institutions, for practitioners to attend and treat those of their cases who are admitted to these institutions." The Conference was considerably exercised as to the exact wording of this resolution. A somewhat similar resolution was passed at last year's Conference, and since that time the Hospitals Committee and the Insurance Acts Committee of the British Medical Association have been occupied with these matters. As far as private and paying patients are concerned, certain alterations made in the hospital policy of the Association by the Representative Body in July will, if effectively applied, do all that seems necessary. As regards non-paying patients in the ordinary wards, the matter is more difficult of adjustment. Inquiries are being made as to the present facilities for general practitioners to have responsibility for their own patients in hospitals, and it would not be surprising to discover that, by means of beds in cottage hospitals and arrangements with other institutions, there are already large districts of the country in which such facilities are not far from adequate. In the largest towns, and in some other urban areas, more opportunity for general practitioners and other private practitioners is highly desirable; but the exceptions that must be made and the conditions that must be arranged in some cases will require the most careful consideration. Meanwhile, such a discussion as that which took place at the Conference, and such a resolution as that which was passed, are timely and valuable. They were in effect, and were intended to be, a demonstration that just now, when the hospital question is in the foreground, and when new arrangements with regard to institutional provision and usage are about to be discussed, the general practitioner or the specialist who is not on the regular staff of a hospital shall not be forgotten, and the needs of his patients who wish him to continue in attendance when it is appropriate for him to do so shall be provided for.

For the last two years the Conference has had for its chairman Dr. E. K. Le Fleming of Dorset. His chairmanship has been a notable success, and the thanks of the Conference were tendered to him very

heartily indeed. His successor is Dr. Cardale of London, whose qualifications for the post, in knowledge and experience, are very high, and to whom, in common with his colleagues, we accord a sincere welcome.

DIAGNOSTIC VALUE OF THE VACCINIA-VARIOLA FLOCCULATION TEST.

THE immunity reactions of filterable viruses still form the subject of acute controversy. The majority of workers are prepared to admit that immunity to a filterable virus is associated with the appearance in the blood of a new and specific activity which can be demonstrated by mixing serum and virus and inoculating the mixture. With a sufficient concentration of serum and appropriate virus such a mixture is innocuous—neutralized—and the specific activity of the serum is spoken of as a neutralizing or viricidal antibody. But beyond this there is no unanimity of opinion, and investigators are sharply divided on the question of the mechanism of this immunity reaction. Some hold that the virus antibody is similar in nature to the bacterial and other antibodies with which we are familiar, and capable of demonstration by the usual *in vitro* reactions. Others deny this, and consider that virus antiserums operate in some obscure and unusual way. M. H. Gordon, who is an exponent of the first school, demonstrated in 1925[1] that both specific complement fixation and flocculation could be obtained with the viruses of vaccinia and variola and their antiserums. Admittedly these reactions required considerable skill and care for their satisfactory demonstration, but the evidence produced by Gordon was quite clear-cut. Schultz and his co-workers[2] have failed to confirm Gordon's findings, and look upon these reactions, when they do occur, as being non-specific and probably caused by the presence of contaminating bacteria in the virus suspensions used as antigens.

The report on the "Diagnostic value of the vaccinia-variola flocculation test," by W. L. Burgess, James Craigie, and W. J. Tulloch, just issued by the Medical Research Council,[3] is a complete vindication of Gordon. These workers produce convincing evidence to show that, with a satisfactory serum, specific flocculation can be obtained with the viruses of vaccinia and small-pox. The two viruses are immunologically identical, of course. The material which they have examined has consisted of the crusts derived from small-pox (50 cases), vaccinia (4 bovine, 5 rabbit, and 2 human), varicella (27 cases), septic rash (1 case), impetigo (1 case). The crusts were weighed, triturated, and suspended in saline, any flocculer material being removed by centrifugalization before using the suspension in the test. It is not the place here to discuss the technical details of this reaction; suffice it to say that these workers used the greatest possible care in order to avoid unequivocal results. In the human cases the result of the test was confirmed by the subsequent history of the patient and of the contacts, and the result of vaccination. The authors conclude that the test is specific, and their evidence certainly entitles them to this conclusion. They have given full consideration to the claim of Schultz and his colleagues, but a series of carefully planned experiments designed to show whether contaminating bacteria—usually staphylococci—could be responsible for the reaction failed to uphold this contention. There seems little doubt that the reaction is a specific one implicating virus and specific antibody. There is a remote possibility that it is heterogenetic, like the Wassermann reaction, and Burgess, Craigie, and Tulloch, with commendable caution, confine themselves to indicating the possibility, and call for further work on this point.

Quite apart from the academic interest attaching to the mechanism of this flocculation reaction, there is the practical importance of such a test and the service which it can render the practising physician. At the present time small-pox in this country is of an extremely mild nature. Not infrequently cases are atypical and difficult to diagnose, particularly so at the commencement of an epidemic. It is in such cases that a specific test of this nature should be of inestimable value. Although this mild small-pox (alastrim; para-small-pox, small-pox minor) has only an insignificant mortality, its control is of considerable economic importance. With the increasing relaxation of specific prophylactic immunization the eradication and limitation of small-pox epidemics turns very largely on early diagnosis. The work of Burgess, Craigie, and Tulloch indicates how the laboratory can participate in making this effective. As the Medical Research Council says in its preface, this report gives an example of the valuable results obtainable by scientific investigation conducted in the field by a medical officer of health in close co-operation with laboratory investigators. "It illustrates also the process of applying to practical ends the results of work which at its beginning had no immediate objective save that of increasing knowledge."

TREATMENT OF BLADDER TUMOURS.

MR. J. B. MACALPINE, in his opening paper on vesical papilloma, read at the Annual Meeting of the British Medical Association at Manchester, and published this week at page 794, has laid stress on the fundamental difficulty of deciding whether a bladder tumour is innocent or malignant. He states that more divergent views have been expressed by clinicians and pathologists on the subject of papilloma of the bladder than on any other tumour affecting the human body. This divergence not only causes difficulty in the differential diagnosis of innocent from malignant growths of the bladder, but it also introduces into the treatment of what has been diagnosed as a papilloma an element of doubt. If a surgeon holds the view that all papillomata in this situation eventually undergo malignant change, his attitude towards treatment must of necessity differ somewhat from that of a surgeon who regards a papilloma as a simple growth that may occur locally, but will never become malignant. And it is to this doubt concerning the fundamental nature of a papilloma that differences in opinion on treatment are in great part due.

It is to our individual experience rather than to a precise knowledge of pathology that we must turn for guidance in this important matter. At the present time we have three main methods of dealing with vesical growths—excision, diathermy, and radium. Mr. Macalpine, in his paper, confines his remarks to the first two of this therapeutic trinity. In each of them he puts on record great advances—in excision through the use of the method of bladder mobilization advocated by Bentley Squier, and in diathermy by the perfecting of various forms of operating cystoscopes that facilitate the task of electro-congulation. Armed with the appropriate instrument, the expert is now in a position to deal cystoscopically with all but the very extensive types of papillomata of the bladder where

better results are to be obtained by the use of open diathermy.

Mr. Macalpine did not find room in his admirable paper for the third line of attack on bladder growths by means of radium. The omission was probably due to the fact that the discussion in the Section of Surgery at Manchester was primarily concerned with papilloma of the bladder, and only dealt incidentally with other growths. But even when papillomata alone are considered, radium therapy would appear to have a place in their treatment. It is not surprising that the great tendency of these growths to recur, and the fear that they may become malignant, have led surgeons to try on them the effect of radium, either alone or in conjunction with other measures. Excellent results have been obtained from burying radium seeds in the base of a bladder growth removed by open operation. In addition, Dr. Hugh Young in America, and Mr. R. Ogier Ward at the London Radium Institute, have developed a technique for implanting radium seeds cystoscopically that is of the very greatest service in dealing with borderline cases unsuited to treatment by means of diathermy. When these ingenious methods become better known, and the facilities for obtaining radon are increased, it is probable that radium therapy will be used in the treatment of bladder growths of every type.

In the meanwhile, a knowledge of the scope and limitation of this form of treatment is being gained, and a technique is being gradually evolved that may be expected to bring it within the powers of anyone who is possessed of an ordinary proficiency in cystoscopy. There are, indeed, very good grounds for believing that the next decade will witness as great an advance in the treatment of bladder growths as has the last.

THE NORMAL CHILD.

The importance of preventive medicine as part of the programme for the general practitioner has now become almost a commonplace. What is perhaps less fully appreciated is the need for accurate knowledge of the normal, so that the earliest departures from health may be recognized and corrected before well-marked symptoms of disease make their appearance. Definition of the normal is in many ways a difficult task, and one which is in danger of being neglected in the training of students. There has recently been in many quarters a plea for a more extensive teaching of clinical physiology. This was made plain at the Annual Meeting of the British Medical Association at Manchester last July, when a discussion on the subject was opened by Professor F. R. Fraser.[1] It is notorious that many medical students begin to forget all about normal standards after they leave the dissecting room and physiological laboratory, and at many children's hospitals, for example, it is well known that welfare centre authorities are inclined to scoff at the lack of knowledge of the normal child which some highly trained paediatricians betray. The paper by Dr. A. Dingwall Fordyce which appears at page 791 in this issue deals with some of the borderline problems in childhood, and his observations raise very pertinently the question of what is a normal child. The search for standards of normality has attracted attention for many years, but while it would seem at first sight an easy matter to collect statistics of normal healthy children, the task proves often to be difficult and complicated. Tables of heights and weights for age are commonly held to supply standards for gauging normality, but even here difficulties arise. Some years ago *The World's Health* published[2] figures obtained by authorities in different countries for heights and weights for age among normal children, and the discrepancies were much too big to be accounted for merely by race. Thus it appeared that the average Belgian boy of 9 was ten pounds less in weight than the English boy of the same age, but the tables for different countries do not always make it clear whether conditions are identical as regards clothing and boots and the estimation of the nearest age. In America further difficulties arise, for if American-born children are accepted as the standard, then children of "all nationalities" in America give quite different figures. Some observers feel that height and weight alone are crude figures, and various indexes of nutrition have been devised to get over this difficulty. Perhaps the best known is the "pelidisi" system of von Pirquet, where a formula connecting the cube root of ten times the weight divided by the sitting height is used. Any of these systems fails to take into account other important factors, such as the general appearance of the child, the colour of the skin, the state of the subcutaneous fat, the lustre of the eyes, and the state of muscular tone, none of which can ever be satisfactorily expressed as a formula. There is no doubt that if borderline conditions of physical health are to be recognized there must be some increased study of these elementary standards, and it is a matter for surprise that in most textbooks of children's diseases in this country, and in most children's hospitals, figures for heights and weights derived from American sources are accepted without reservation. On the mental side the matter is even less satisfactory in many ways. The public has heard so much about the "problem child" that, as Dr. Dingwall Fordyce says, "we rarely see a child who is not described as nervous." In studying the psychology of children there is a tendency to ascribe all behaviour which is the least bit out of the "ordinary" to some mental warp or perversion, and there is a grave danger of forgetting that a child who is never "naughty" is much more likely to be mentally abnormal than the boisterous "naughty" child whom so many psychologists regard as requiring some sort of analytic treatment. Indeed, even abnormal naughtiness may occur in normal children, and the late John Thomson wrote on this subject, as Dr. Dingwall Fordyce points out. Nowadays abnormal naughtiness may be too lightly ascribed to a previous attack of supposed encephalitis; such an attitude is akin to that of persons who uphold the defence of kleptomania in deliberate shoplifting. A close study of the psychological development of the child is necessary, and should not be left entirely in the hands of educationists and skilled novelists. The normal child is by no means a rare phenomenon; there is no scarcity of material, and on both the physical and the mental side research into normal standards is still very necessary. It is becoming increasingly important for the practitioner to study borderlines of health at all ages, and the background of normality must be satisfactorily defined if such study is to be successful in preventing disease.

SLEEP IN HOSPITALS.

In the wards of a well-administered hospital all the routine activities are carried out strictly by the clock. It is therefore a matter of some interest to consider what are the pivotal events in the hospital day from which all the rest are calculated, and whether, by making any change in the hours fixed for their occurrence, the comfort of patients in hospital may be enhanced. What one might call "zero hour" in hospital is the moment when the resident physician or surgeon in charge begins his morning round. Before this hour it is expected, and rightly, that all preparations for his visit shall be complete—the patients washed, routine treatments administered, and the work of cleaning the wards completed. These tasks have to be divided equitably between the day and night nursing staffs; it would be impossible to complete them if they all had to be

undertaken by the day staff, and even if it were this would mean that the day nurses would be so heavily burdened with duties as to run a serious risk of breakdown in health. Before zero hour, therefore, there is another pivotal moment in the hospital day—namely, the time fixed for the change of the day and night nursing staffs. If, as is at present the rule in most hospitals, the bulk of the routine tasks has to be completed by the night staff before the day staff comes on duty, the hospital work must begin at a very early hour, and the patients in consequence have to be roused from their sleep much earlier than they would be in their own homes. The adage "Early to bed, early to rise," is applied in hospital too literally for most patients' comfort; perhaps when they are in health early rising may help to keep them fit, but when they are sick any routine which has the effect of curtailing sleep may be detrimental, not only to their comfort, but to their progress towards recovery. In pre-Listerian days the chief horror of hospitals was sepsis; to-day it is what many patients regard as the nurses' morbid passion for cleanliness. Their main impression of a hospital (and often of a nursing home too) is a place where they are likely to be roused at some incredible hour for nothing better than to be washed. Some of them have not seen the dawn for years, and have no desire to learn what it looks like through hospital windows. We are therefore glad to learn that the authorities of the Middlesex Hospital have just introduced a new rule by which all patients are to be given breakfast not earlier than 7 a.m., and are not to be washed or disturbed before this hour, except for urgent medical reasons. To make possible this reform—in which the matron, sisters, and nurses are loyally co-operating—it has been necessary to effect a substantial redistribution of duties as between the day and night nursing staffs, and to make it a rule that the visits of the medical officers should not begin before 10 a.m. The hospital authorities believe and hope that their example will be followed throughout Great Britain, and we sincerely trust that this may prove to be the case.

UNDULANT AND ABORTUS FEVERS.

FOR many years the practitioner in temperate climates has been aware that around the Mediterranean and in connexion with goats there exists a human fever which was investigated by Bruce. The disease was for long thought to have no particular interest except round the Mediterranean Sea, and probably few in Northern Europe, in America, or elsewhere, noticed that the Maltese objected to the name "Malta fever," as well as that the geographical limitations suggested by the name "Mediterranean fever" had been found not to apply, and that the name "undulant fever" was coming into use. It may be doubted whether the new name is a happy one—any happier, indeed, than the term "continued fever," which is now disappearing. The issue by the Ministry of Health of No. 56 of its Reports on Public Health and Medical Subjects[1] has considerable interest in Britain at the present time, but there would seem to have been little need to recapitulate the history of true Mediterranean fever from the time of its first recognition in the Mediterranean area. The importance of the undulant fever problem from the British point of view can be quite shortly stated. It became noticeable that cases of disease, recognizable as Mediterranean fever, were occurring outside the area first supposed to limit that complaint, and in places little or not at all associated with goats. Evans established the fact in the United States of America that the causal organism of Malta fever, as recognized by Bruce and called *Micrococcus melitensis*, is very closely allied to, and indistinguishable morphologically from, the organism of infectious abortion of cattle, commonly called the *Bacillus abortus* of Bang. Both have been given the generic name Brucella, some speaking of separate species under the names of *Br. melitensis* and *Br. abortus*, others putting both in the same species as *Br. melitensis* and recognizing var. *abortus* and var. *melitensis*, these distinctions resting on serological reactions. Infectious abortion of cattle is known to be widespread in Britain and most other countries of the world, and there has been, in the last year or two, a steady stream of records from many countries of obscure cases of human fever in which the blood agglutinated *Br. abortus* in high dilutions; in many of these cases haemoculture, guinea-pig inoculations, and elaborate serological tests left no doubt that human infection with the organism of infectious abortion of cattle was by no means rare. In addition to these discoveries, the milk of cows has been found in many countries to contain *Br. abortus*, and there is abundant evidence that the disease can be contracted by direct contact with infected animals—cow, horse, sheep, pig, and others. Only a few cases of undulant fever indubitably contracted in Britain from other sources than goats have been reported, and Captain W. Dalrymple-Champneys, the author of the Ministry's report, puts the question, Is the disease really rare in Britain, or is it not being recognized? Indeed, he goes further, and canvasses the question whether recent discoveries all over the world indicate spread of the disease, or spread of knowledge of the disease and therefore its recognition. No extensive examination of blood samples for serological reactions with Brucella organisms seems to have been made in Britain, but in some tests a by no means negligible proportion of samples of market milk have been found to contain *Br. abortus*. The clinical phenomena exhibited by persons with undoubted Brucella infection are very variable indeed—so variable that use of the name "undulant fever" is misleading. It seems likely that once the possibility of obscure and long-continued fever being due to Brucella infection is widely known, evidence of the presence of the disease in Britain will be forthcoming. There is on record no well-established case of human abortion due to specific infection with *Br. abortus*. The literature of the subject has become enormous; the present report gives 457 references, which the author does not present as a complete bibliography. Those who are well acquainted with recent medical literature will discover little new in the report; those who have regarded undulant fever as a tropical or subtropical disease, and infectious abortion of cattle as a purely veterinary matter, will, however, find present knowledge and opinion admirably summarized, and may well obtain an explanation of cases which have been very puzzling and intractable. Abortus infections in man are rarely fatal; the disease is generally of moderate severity, tending to chronicity, and ambulant cases occur. Pasteurization renders milk safe, and herds can be freed from the disease by elimination of the infected, who often secrete *Br. abortus* in milk and urine while apparently in perfect health.

SILICOSIS: MEDICAL ARRANGEMENTS.

THE committee, consisting of Dr. J. C. Bridge, Dr. F. J. H. Coutts, and Professor Arthur Hall, which was appointed to advise as to the medical arrangements which could be made for the diagnosis of silicosis and for carrying out any periodic or other medical examinations of workers in any industry involving risk of silicosis has now issued its report.[1] More than one complaint is made of the difficulty of the task set. So complicated does the subject appear to be that the report envisages the possibility of the following classes of medical men being called on either to visit a works or to examine a workman where the risk is attendant;

[1] Report of the Departmental Committee appointed by the Secretary of State to advise as to the Medical Arrangements which could be made for the Diagnosis of Silicosis. London: H.M. Stationery Office. 1929. 6d. net.

(1) the certifying factory surgeon (immemorial rights); (2) the tuberculosis officer (to make the initial examination of the newly employed); (3) the two members of the medical board (for whom centres will be necessary, the first in Sheffield, Bristol, and Newcastle-on-Tyne, and later at Stoke-on-Trent, Birmingham, Manchester, and Glasgow); (4) the chief medical officer (the appointment of one is recommended); (5) the medical radiologist; (6) the employer's medical man; (7) the workman's medical man; (8) H.M. Medical Inspector of Factories. The suggestion put forward by the witnesses for the Trade Union Congress General Council that, in addition, a medical board of appeal should be set up on lines similar to that in existence under the Fibroid Phthisis Act of 1925 in South Africa was not encouraged. The committee really plumps for an extension of the system of medical boards, the existing one appointed under the Refractories Industries (Silicosis) Scheme having carried out its duties with commendable success. The last paragraph of the report contains a strong plea for research into silicosis on the clinical side, on the pathological and experimental side, and towards ascertaining the concentrations of dust likely to cause injury, establishing a ready method of estimation of dust concentration for field work, and exploring methods of dust control. Here the committee recommends, as is right, that the research should embrace not only silicosis, but the pneumonoconioses in general. A weak point in the report appears to be the absence of figures—except for well-known silicosis-producing industries—showing not only the number of persons brought in under the recently issued Various Industries (Silicosis) Scheme, but also the number of industries and processes. All that is said under this head is: "We are convinced that silicosis . . . occurs to some extent in a number of industries and occupations where its presence has not been suspected." May there not also be many industries and occupations where a little silica is used without any risk whatever? It might be best to take no action on the report until more information is vouchsafed on this important aspect, and until the prospective conference of experts in Johannesburg next spring has been held.

CONTROL OF EXCESSIVE NOISE BY LEGISLATION.

The Motor Car (Excessive Noise) Regulations, which came into force on August 1st, make it an offence for any person to use, or permit to be used, any motor car, or trailer driven by a motor car, which, by reason of its design, constitution, lack of repair, or load, creates any excessive noise. When, following the recommendations made in the report of the conference on road traffic noises and priority of traffic at cross roads, these regulations were announced, we suggested (June 22nd, p. 1131) that a certain difficulty might arise through the fact that the onus of deciding what constitutes "excessive noise" was to be placed in the first instance on the police, and then on the magistrates who would have to deal with charges under the regulations. Subjective impressions are notably unreliable, and in the absence of a precise definition of "excessive noise," involving the use of some objective standard, the fate of the motorist would seem to depend upon the private judgement of the policeman, and, what is even more unsatisfactory, the decision of a magistrate who has had no opportunity of hearing the noise at all. While, however, the noise which is the subject of complaint cannot, as it were, be brought into court, it is possible by means of an accurate description of a vehicle or of its load to establish a reasonable probability that it is capable of making a noise which, by any reasonable objective standard, would be classed as excessive. Such evidence, indeed, is circumstantial, but the validity of circumstantial evidence is, after all, recognized in English law, even in establishing charges of greater seriousness than the infringement of traffic regulations. In any case it would seem that, pending a definition of "excessive noise" on the lines we have suggested, such evidence might be of great service to magistrates faced with the responsibility of administering the law as it stands. In one of our courts recently there were heard five summonses under the regulations, and in each case evidence of defect in the vehicle responsible, or of careless loading, was brought forward by the police. The magistrate, in imposing fines, said that he was determined to try to put an end to such noises in the streets, especially on Sunday mornings. We may hope that he will take an equally serious view of excessive noise at other times, the need for quiet of persons engaged in their ordinary occupations demanding sometimes as much consideration as the need of persons enjoying their week-end rest. In New York the problem is at present engaging serious attention, and according to a message to the *Times* from its correspondent (October 23rd), a small group of people, each eminent in some field connected with the problems, has been appointed by the Health Department to act as a noise commission. The commission includes a former president of the New York Board of Education, two neurologists, and a research engineer, and it will have at its disposal all the facilities of the Health Department and the best available laboratory equipment. While it is hoped that its researches will enable the authorities, by new legislation, to handle the wider aspects of the problem, there is also an immediate demand for the alleviation, under the existing ordinances, of the more strident noise-making activities which have increased with special rapidity during the past few years. In discussing the fundamentals of the problem the Health Commissioner says: "We need a complete classification of noises and a tabulation of their intensity geographically arranged. We need a scientific statement of the effect of noise on the human being. We should have scientific measurements of certain types of noises and recommendations as to what constitutes the borderline of reasonable, inevitable noise and unreasonable noise. We further suggest a thorough investigation of the possibilities of constructing buildings with a high capacity for absorbing sound." We may hope that the noise commission in New York will, as a result of its inquiry, be able to suggest practical proposals for dealing with the problems included in its terms of reference. Every civilized country to-day is confronted with similar problems, and it is all to the good that as many trained minds as possible should be applied to their solution.

MAN AND MICROBE.

For nearly fifty years Sir William Collins, as a sanitarian interested in the control of specific diseases, has emphasized the importance of man—the soil on which these diseases flourish—not, as a lesser advocate might have done, with the purpose of discrediting the seed, but to correct the perspective of those who lose sight of man "amid the luxuriant and magnificent flora of the bacteriological laboratory." "We are," he writes in a preface to *The Man versus the Microbe*,[1] "rather too apt in our 'tithing of mint, anise and cumin,' and in the cult of the microbe, to forget or ignore 'the weightier matters of the law' of healthy living." And again later: "it may be permissible to inquire, with all humility, whether bacteriology has adequately explained the etiology of even our commoner zymotic diseases in the sense of identifying, beyond doubt or dispute, a specific organism as the *vera causa* of each of them? It may be respectfully asked whether the influences attributed to predisposition, to sanitary environment, to the resistant power of health, to the *vis medicatrix naturæ*, have really been shown up as mere moonshine?" In the

[1] *The Man versus the Microbe.* Five Presidential Addresses to the Sanitary Inspectors' Association. By Sir William Job Collins, K.C.V.O., M.S., M.D., F.R.C.S. 1929. Surrey Fine Art Press, Redhill. Price 1s.

course of the five addresses which form the subject-matter of his pamphlet Sir William Collins poses these questions again and again, and adduces cogent reasons for his faith that the possibilities of environment are not exhausted by the "confectionery of the laboratory." Thus, taking for example typhus fever, regarded by the older sanitarians as a "filth" disease, he argues that while no micro-organism has yet been established as its cause, no disease has proved to be more definitely related to bad hygiene, or more amenable to eradication by ordinary sanitary measures and decent conditions of living. "You may speak of its hypothetical organism as louse-borne," he writes; "you may describe it as ultra-visible or a filter passer, but the disease is, nevertheless, vanquished by the gospel of soap and water, and yields submissively to the Chadwick touch." He is far from suggesting that the community must sell itself body and soul to those who wield the communal scrubbing brush. Drainage, water supply, the control of infectious disease and dangerous mental disease, the abatement of nuisances—admittedly these should be the concern of the community acting through a responsible and representative authority; but the public, in matters which are not communal in their nature, will, he believes, rightly resent either a State or a municipal bureaucracy. We may be sure that, for all his sanitarian principles, Sir William Collins would not feel at home in a world smelling of institutional soap. He holds, with John Stuart Mill, that "the principle of freedom cannot require that a man should be free not to be free," and when he advocates limitation of individual freedom it is only in the interests of disciplined free-will and self-control. He writes with wit, scholarship, and distinction, and enlivens his theme with a wealth of epigram, historical detail, and literary allusion. It is a pleasure to read his collected addresses, if only for the attractive thumbnail sketches they contain of Koch, Chadwick, Pasteur, Semmelweis, and many others who have helped man to understand, not merely the microbe, but himself.

DAVID FERRIER.

THE full text of the first Ferrier Lecture, on "Some functional problems attaching to convergence," delivered by Sir Charles Sherrington on June 20th last, has now appeared in the *Proceedings of the Royal Society* (*B*, *vol.* 105, 1929). A summary was published in our issue of June 22nd (p. 1136). In his introductory paragraph the lecturer said: "This occasion bears tribute to a name which marks a turning-point in the story of the study of the nervous system. David Ferrier, with his pursuit of localized function in the brain, took neurology into a new period. Thence onward functional neurology could never resign itself again to picturing the cerebral cortex as an uncharted sea with for its one accredited feature unanalysed uniformity. It was a fitting step, promoted by some whom we welcome here to-day, to assure as from to-day an enduringly recurrent opportunity for spoken remembrance of him. And for David Ferrier remembrance could take, I think, no shape more congenial to himself than that of the foundation of a lecture bearing his name at this Society. Here his picture, the gift of Lady Ferrier, re-images to us not a little of that genial and penetrative vivacity which was part of him. And it was in this room, fifty-five years ago, and to this Society, that he described first those memorable experiments which fascinated scientific attention then and now stand as starting-point for contributory knowledge from surely every quarter of the civilized world. . . . It has seemed to me that to recall in detail, when but a short while ago he was still with us, the history of Ferrier's scientific work, and to recall it before this audience, would be to retell familiar matter. It therefore would seem to me that a form our tribute to him might preferably take to-day might be presentment—slight and imperfect though it be—of some current neurological research. His own unflagging interest in such themes permits the thought that such might please himself. Ferrier's work ranged over the nervous system widely. It furnished illustrations of how to each region of that system two questions may be addressed: Toward what aim does this part work? and, In what way is what it is doing done?"

SOCIETY OF APOTHECARIES.

Two interesting ceremonies took place after a Livery Dinner given on the evening of October 29th by the Society of Apothecaries of London in their Hall at Blackfriars, with the Master, Lieut.-Colonel C. T. Samman, in the chair. One was the presentation of the Society's gold medal for pharmacology and therapeutics lately awarded to Professor John Jacob Abel of Johns Hopkins Hospital, Baltimore. The medal was received on his behalf by Mr. Ray Atherton, Chargé d'Affaires of the United States, who expressed the Ambassador's regret at his inability to be present, and read an appreciative message from Professor Abel. The second ceremony was the conferment upon Sir Humphry Rolleston, Bt., G.C.V.O., of the honorary freedom of the Society. Sir Humphry was presented to the Master to receive this honour by his colleague at Cambridge, Professor W. E. Dixon, F.R.S., acting as Deputy Senior Warden in the absence of Sir George Buchanan. The customary toast of "The Royal Colleges" was then proposed by Dr. Cecil Wall, and Sir John Rose Bradford, *President* of the Royal College of Physicians, and Sir Holburt Waring, representing the Royal College of Surgeons, replied. The health of "The Guests" was proposed by the Junior Warden, Colonel E. C. Freeman, who coupled with this toast the names of Lord Dawson of Penn, President of the Royal Society of Medicine, and Lord Riddell, President of the Medico-Legal Society. Other distinguished guests present were Professor A. H. Burgess, President of the British Medical Association, Sir John Bland-Sutton, Sir George Makins, Dr. A. E. Giles, Master of the Drapers' Company, and the Directors-General of the Royal Naval Medical Service and the Army Medical Service.

NATIONAL RADIUM TRUST.

A MEETING of the National Radium Trust was held on October 23rd at the Privy Council Office, under the chairmanship of Lord Parmoor. The matters under consideration included the arrangements which are being completed for the purchase of radium, the financial and administrative organization of the Trust, and questions relating to the work of the Radium Commission. Questions arising in regard to the purchase of radium on behalf of individual institutions were deferred for consideration at a subsequent meeting. The Trust appointed the Hon. R. H. Brand to be its honorary financial adviser, and under Article 2 (2) of the Charter two members of the Commission—Mr. Comyns Berkeley and Dr. J. W. W. Morrison—were co-opted to be members of the Trust.

VISCOUNT GREY OF FALLODON will deliver the Rickman Godlee Lecture in the Great Hall of University College, London, on Thursday next, November 7th, at 5.30 p.m. His subject is "Natural history, the pleasure and purpose of observation." The chair will be taken by Sir John Rose Bradford, President of the Royal College of Physicians.

WE regret to announce the death, on October 26th, at his home in Paris, of Professor Theodore Martin Tuffier, K.B.E., F.R.C.S. (Hon.), the eminent French surgeon. We hope to publish an obituary notice in an early issue.

THE ENGLAND OF HARVEY.

EXTRACTS FROM SIR WILMOT HERRINGHAM'S HARVEIAN ORATION.

The annual Harveian Oration before the Royal College of Physicians of London was delivered on St. Luke's Day, October 18th, by Sir Wilmot Herringham, K.C.M.G., C.B., M.D., Fellow of the College and consulting physician to St. Bartholomew's Hospital.

After quoting some little-known or forgotten passages in the life of William Harvey, and describing the characters and fortunes of members of the Harvey family, the Orator passed to a consideration of some of the conditions of Harvey's own life.

School and University.

Harvey was brought up at the Cathedral School of Canterbury, one of the best in the country. At that date Latin was the univ[illegible] the language of learned men, the [illegible] and of travel. Every bachelor of [illegible] in Latin; the young barristers used it in their moots in the Inns of Court; the accounts of the royal household, and even some of the merchants' accounts, were kept in it. Accordingly it was the aim of every good school to make its boys not only able to read but able to speak Latin, and in the statutes of Canterbury dated 1541 it is ordered that the boys, whether at work or play, should speak nothing but Latin and Greek; but Greek was rarely taught in schools. You may remember that Montaigne, who lived about that time, was not allowed to speak any language but Latin until he was 6. Greek was brought into the schools by the Calvinists who returned to England on the accession of Elizabeth. For them Greek and Hebrew were the two sacred languages, and for the study of the Bible Greek became common in the schools, and even Hebrew was sometimes taught.

We may therefore confidently suppose that Harvey went to Cambridge able not only to read, but also to speak Latin after a fashion, and with some knowledge of Greek. The old free university had given place to a system of colleges and halls founded to train priests by pious benefactors, of whom the greatest, though not the first, was my own founder, William of Wykeham. The life was hard and the teaching narrow. Into these ecclesiastical seminaries the classic revival of the fifteenth century in Italy, patronized by Humphrey, Duke of Gloucester, and other great men, brought a fresh inspiration. At Oxford, Linacre and Groeyn, and in London, More, were as good Grecians as any in Europe. Wolsey and Fox and Henry VIII all encouraged and endowed classical studies. But the classics, and especially Greek, were attacked for their paganism both by the old religion and the new. In Oxford, Greek soon fell into contempt. At Cambridge, under Cheke and Smith, it held better. By Harvey's time it was re-established. Spenser, who went up in 1570, was a Platonist, and Harvey was devoted to Aristotle.

But meanwhile the universities had fallen on evil times. The Church had been plundered by the Crown, and also by its own patrons, both lay and ecclesiastic. Spenser, in *Mother Hubberd's Tale*, describes the lay patron bargaining with an unfortunate clergyman, before he would present him to a £40 living, that he should resign half the income to the squire's son. The upper clergy were pluralists. One man might hold several benefices. The lower clergy were accordingly half starved, and as a natural consequence were grossly ignorant, careless of their duties, and sometimes drunken and corrupt. Scandalous benefices beget scandalous ministers. It was this state of things that gave the Calvinist attack such strength. The Church fell as much by its own faults as by the virtues of the Calvinists.

The absence of decent prospects in the ministry led to a great falling off in the number of students. Added to this, the destruction of the monasteries had deprived the universities of the large numbers of scholars whom they sent up with exhibitions. In the middle of the sixteenth century the numbers had fallen to a few hundreds, nearly all the halls were closed, and the colleges were half empty. Further, the ecclesiastical character of the universities laid them open to interference by the head of the Church, now the monarch. By voting for the divorce they had placated Henry VIII. But under Edward VI all the heads and professors who sympathized with the old religion were expelled. Under Mary the process was renewed in the opposite direction. Eleven heads were expelled in Cambridge alone. Under Elizabeth the Act of Supremacy was enforced, with a similar expulsion of all Romanists, and the universities became violently Calvinist.

In 1573 the vice-chancellor of Cambridge and two other leading dons broke into Caius Chapel and destroyed all the decorations with which John Caius, who was a high churchman, if not a papist, had beautified it. In 1595 Whitgift, the Archbishop of Canterbury, and a synod of bishops drew up the Lambeth Articles, of which the following are specimens:

> God, from all Eternity, hath predestined certain men unto life: certain men He hath reprobated.
>
> The moving cause of Predestination unto Life is not Faith or Good Works or "anything that is in the person predestinated," but only the Goodwill and Pleasure of God.
>
> There is predetermined a certain number of the Predestinate, which can neither be augmented nor diminished.
>
> Those who are not predestinated to salvation shall be necessarily damned for their sins.
>
> Saving Grace is not given . . . to all men by which they may be saved if they will.
>
> No man can come unto Christ unless the Father shall draw him; and all men are not drawn by the Father.
>
> It is not in the will or power of everyone to be saved.

This cheerful view of the future was, however, too much for Elizabeth. She sent for her little black husband, as she called Whitgift, and, after giving him what, in those days, was called a rattling, told him to withdraw the articles altogether, which he had to do. James, who loathed the Scottish Calvinists, threw all his weight on the same side. In 1611 Laud, who, in spite of violent opposition, had led a growing High Church party in Oxford, was elected president of St. John's, and by 1622 Oxford had become anti-Calvinist. Cambridge followed suit, though considerably later.

Meanwhile, however, a great change had taken place in the material circumstances of the universities. Elizabeth, who loved to air her accomplishments, began the system of royal visits to the universities with all their solemn puerilities, which was continued by James and Charles. She made the universities fashionable. Donations were made by her courtiers, and the numbers rose, at the end of her reign, to 2,500 at Oxford and nearly as many at Cambridge. Venn says that 1590 to 1640 was the zenith of the universities until quite recent times. The result was not an unmixed blessing. The rich youth who now flocked in brought with them the manners of rich men, and for many years the statute-books are full of decrees against extravagance in dress, drunkenness, gambling, insubordination, and such unseemly sports as football. An undergraduate twice convicted was to be whipped.

All this had, however, little effect upon the poorer students. Their life continued as hard and scanty as it was before. Harvey went to Caius with a Matthew Parker scholarship. The capital endowment of it was £61 13s. 4d. Elizabeth, in 1559, made an injunction that all clergy whose benefices were worth £100 or more should, for every £100 of their income, contribute £3 6s. 8d. as an exhibition for a scholar at the universities. Under James existing professorships received additional revenue, among which the

chair of physic at Oxford was augmented by the mastership of Ewelme Hospital, and fresh chairs were set up in mathematics, in natural and in moral philosophy, and in anatomy. All these at Oxford. Similar improvements, no doubt, took place at Cambridge.

During the Rebellion both universities were at first Royalist, for Cambridge was preparing to send its plate when it was prevented by Cromwell, but Scarborough was expelled from Caius for his loyalty, and the university had by this time been overpowered by the Parliament. Oxford was loyalist throughout, and after the King's death refused to take the oath prescribed by Parliament, for which it was punished by a visitation under Philip, Earl of Montgomery and Pembroke, the chancellor who succeeded Hertford. On his death in 1650 Cromwell became chancellor, and under his tolerant rule Oxford had comparative rest.

Of Harvey's feeling to Cambridge we know nothing. He is not known to have returned there after taking his degree, though, as he was at Newmarket in 1636 attending the young Elector, it is possible he was present at some ceremony.

Medical Practice.

To understand the England of Harvey we have to imagine a society to which science was unknown. To us the growth of knowledge by observation and experiment is a commonplace. Every morning we read the discussion of some scientific society, or are told of some new discovery. In Harvey's time the few sciences that existed were little removed from magic. The great majority, including all the sciences of living things from botany to sociology, did not exist at all. Alone in the great mind of Bacon had the real meaning of science been grasped and the immensity of its future conceived. Men were still content to ascribe the action of the liver or the brain to spirits, and the cause of disease to disordered humours. Not only had they not yet comprehended that such operations could be examined by physical methods, but they looked upon such attempts to continue the spirit of Galen and other authorities by correcting their mistakes exactly as the Roman Church looked upon the Reformation.

Bacon, in his *Advancement of Learning*, published in 1604, the year that Harvey took his degree, describes with great shrewdness the difficulties of medical practice, and sums up:

> "So then the subject being so variable hath made the art by consequence more conjectural, and the art being conjectural hath made so much the more place to be left for imposture.
>
> "And therefore I cannot much blame physicians that they use commonly to intend some other art or practice which they fancy more than their profession. For you shall have of them antiquaries, poets, humanists, statesmen, merchants, divines, and in every of these better seen than in their profession; and no doubt upon this ground, that they find mediocrity and excellence *in their art maketh no difference in profit* or reputation towards their fortunes.
>
> "Medicine is a science which hath been, as we said, more professed than laboured, and yet more laboured than advanced,"

and the reasons that he gives are "the discontinuance of the ancient and serious diligence of Hippocrates" in taking notes of cases, the neglect of morbid anatomy, and the absence of exact inquiry into the effect of drugs.

In Bacon's own lifetime two men, Mayerne and Harvey—partly, we may think, owing to Bacon's criticism, and partly, no doubt, because they *shared in the scientific* spirit that was just beginning to awake—worked exactly as Bacon advised. We have Mayerne's clinical and post-mortem notes in his own beautiful handwriting here in the library. Harvey's, to which he himself alludes, are unfortunately lost, but he had them in 1648 when the letters to Riolan were published, and it is possible they may yet be found. These two men revived the old Hippocratic tradition, and they were followed, after the Restoration, by Willis, Lower, Glisson, and Sydenham.

It is difficult to judge exactly what Harvey's position was in the general estimation. He attended Bacon himself, and also his successor, Lord Keeper Williams, Bishop of Lincoln; and the latter's biographer, Bishop Hacket, tells how "that great secretary of nature, Dr. William Harvey," saved William's life in what seems to have been a dangerous attack of enteric in 1621. We know the names of other patients, Sir Thomas Thynne and Sir Thomas Sandys, from certificates that he gives of their unfitness to travel. He also attended the Lord Treasurer Weston, who was laid up with an attack of the stone at York during Charles's expedition to Scotland in 1633. He says he lost practice by publishing the *De Motu*, but he must have regained it when he was made Physician to the Household. He practised medicine, surgery, and, it seems by his notes in the *De Generatione*, diseases of women especially.

The title of Medicus Regius, meaning physician to either James or Charles or their Queens, was held by no fewer than sixteen men besides Harvey. Five of them were knighted, which Harvey was not. Sir Matthew Lister was physician to Henrietta Maria, and when she was confined at Exeter in 1644, he and Mayerne went down to see her. But the great man of the time was Sir Theodore Turquet de Mayerne.

The Sciences and the Arts.

There was a small circle of men who sought relief from the troubles of the times by working at natural science at Oxford. Members of the group were Wallis, Savillian professor of geometry, Willis, professor of natural philosophy, Robert Boyle the chemist, and Wilkins, warden of Wadham and Cromwell's brother-in-law. They had been accustomed to meet in London up to 1648, so that Harvey did not form one of the Oxford group, and they were the nucleus of the Royal Society, incorporated by Charles II in 1660. It is curious that no mention of Harvey as a discoverer occurs in Sprat's *History of the Royal Society*.

Of other sciences, physics had produced in 1600 the work of Gilbert on the lodestone, which is of the first class, and in many points is a standard at the present day. Astronomy had made great advances under Kepler, who died in 1630, Galileo was lecturing at Padua when Harvey was there, and in 1636 a poor Lancashire parson called Horrocks for the first time observed the transit of Venus. Napier invented logarithms in 1614. It is curious that the only references that Harvey makes to astronomy are to disparage its methods in comparison with the direct observation of anatomy.

In striking contrast to the infantile condition of science was the maturity of art and literature. In Harvey's time there was a great enthusiasm for painting and sculpture. Charles is said to have had the finest collection of pictures in Europe. Arundel was second only to the King. Denbigh also collected. But they were not alone. Buckingham and many others were collectors, and it was not confined to court circles. Colonel Hutchinson was a good judge, and Mrs. Cromwell had a collection of portraits. There was no native school, though Dobson painted good portraits, but the seventeenth century was the age of the Dutch, Flemish, and Spanish schools, and collectors can seldom have had such chances. Vandyck lived for several years at different times in England, and Rubens was sent over as ambassador.

Harvey was undoubtedly interested in painting, for Charles gave him a commission to buy for him in Italy, and when he escaped from quarantine he travelled to Florence and Rome under the guidance of Mr. Petty, a clergyman who collected in Italy and the Near East for Arundel. By his introductions he was very courteously treated by the Grand Duke of Tuscany, who was a scientific man, and by Cardinal Barberini at Rome, but he was an amateur at buying, and failed to get anything of value.

Another art that was universally cultivated then was music. From 1580 to 1640 English music was at its best. The Puritans stopped ecclesiastical music, but rather because it was favoured by the bishops than that they themselves objected to it. There was a good deal of destruction of organs and church instruments at the hands of the soldiers; but it was not widespread, and the Puritans themselves sang psalms. Secular music was never thought wrong by anyone, and it is quite untrue to say that the Puritans set their faces against it. Bunyan, Milton, Cromwell, and Colonel Hutchinson were all devoted to music, and Colonel Hutchinson to dancing also, yet no one was a stricter Puritan than he. Cromwell was the first man who provided a court concert as an entertainment

for his friends. His ambassador to Sweden, Whitelock, took musicians with him, and was himself a performer. In fact, in those days it was a regular part of a gentleman's education, whatever his religion or his politics.

But of course nothing equals in significance the fact that Harvey's life was practically coterminous with what we term Elizabethan literature—the greatest outburst of literary genius that the world has ever seen. The first three books of the *Faerie Queene* were published when Harvey was 11 years old, and Herrick's *Hesperides* in 1648, when he was 70, and between those dates lie all the greatest names in English literature.

I have wondered whether, in their early married life, Dr. and Mrs. Harvey took a boat across to Bankside, where Shakespeare's plays were being given at the Globe up to 1613. I have wondered, too, what Harvey thought of the *Religio Medici*, which was circulating in MS. in 1636, and what he would have said to Browne if they had met. We know Browne's opinion of the *De Motu*. In recommending it to Dr. Henry Power, he speaks of it as a greater discovery than that of Columbus.

Harvey quotes Virgil and Terence, but he gives no sign that he had ever read or heard of the great writers of his own day. But a writer on scientific subjects can hardly be expected to quote contemporary poetry. We need not, therefore, suppose that Harvey's silence means that he was without knowledge of the wonderful art around him; on the contrary, we know that he mixed with men who held it in the highest honour. Charles kept a Shakespeare in his bedroom. But in the first half of the seventeenth century the interest of most men was turned not to literature, nor to painting, nor to science, but to two subjects, which of all others are the most inimical to the cultivation of science or of art—politics and religion.

Politics and Religion.

The chief social change in the sixteenth century was the rise in wealth and influence of the upper middle class, including the squires in the country and the merchants in the towns. Both were of the same stock, for younger sons went into trade, and merchants who succeeded bought land. Some families combined both. The squires profited by the ruin, in the Wars of the Roses, of the old nobility, whose estates they bought, and also by grants and cheap leases of the abbey lands under Henry VIII; both they and the merchants, by the great increase of the cloth trade which began under Edward IV, increased under Henry, and continued with fluctuations throughout the century. It led to a great demand for sheep pasture, and this in turn to a fourfold rise in rents, as related by Latimer, and to a large reduction of arable land to pasture, as described in *Utopia*. But this again threw so many labourers out of work that Elizabeth was obliged to pass a new Poor Law to save them from starvation. The House of Commons was practically filled by the squires, the merchants, and the lawyers, who sprang from both.

The Tudors, the ablest and the only native dynasty we have ever had, knew the House of Commons thoroughly, and except in matters of religion, managed them with great tact. But Elizabeth, with all her prestige and popularity, so clearly recognized their reluctance to grant money that she practised the most sordid parsimony, suffered her great public servants to die in poverty, and, sooner than ask for supplies, poisoned with bad victuals the soldiers and sailors who saved England.

James, coming as a foreigner from a country where the middle classes hardly existed, and ignorant of our great political struggles in past centuries, was as entirely unable to recognize the position of the Commons as he was personally incapable of dealing with them. His silly profusion brought him rapidly to poverty, and he presented the ironic spectacle of a King blustering about his sovereign power and in the same breath begging for money to pay his tradesmen. No wonder that the Commons lost their loyalty to the Crown. In 1621 James tore out of the Commons' journals the dignified declaration in which they stated their rights and liberties, and in 1625 he died at the end of the negotiations for the Spanish match, an enterprise begun with the usual Stuart disregard of the national feeling, pursued with the usual Stuart duplicity, and ending in the usual Stuart ill success.

For Charles there was less excuse. He had taken a prominent part in politics for some years before his accession, and had abundant opportunity to learn. But if a man cannot learn by experience, wherewithal can he be instructed? He was, in his first years, dominated by his evil genius, Buckingham, and though the Commons undoubtedly treated him very badly at that time, yet surely no man could have treated them with less tact than Charles. A Venetian wrote of him: "This King is so framed by Constitution that he can never oblige any man by word or deed." When he finally decided to govern without Parliament his arbitrary measures, if not against the letter of the law—and it must be remembered that he had the warrant of most of his judges for what he did—were so completely against the spirit both of the Constitution and of the Petition of Right, which he had recently signed, that he irretrievably alienated both Parliament and the country. Moreover, both parties, the King and the Commons, were equally justified in distrusting each other. If the Commons had good cause to distrust Charles—and they certainly had—Charles had equally good grounds to distrust them. Faction ran high; what was voted on Monday was rescinded on Tuesday, and at the end the majority who wished to continue negotiations were expelled from the House by the minority and the army.

But the desire for political liberty had small influence compared with the violence of religious fanaticism. Religious grievances were invariably placed first in all the transactions of the House of Commons. Henry VIII, to gratify his own passions, had led the nation to revolt from the Pope. But beyond a change of supremacy the religious practice of England was, for many years, little altered. Gradually, however, and more rapidly after the Marian persecution, Calvinism spread over the whole of England and Scotland. The City of London and the universities were its chief strongholds. It is difficult for us to understand its appeal. Probably few Fellows of the College have laboured under the conviction of original sin and the certainty of damnation which clouded Cromwell's early manhood, or have experienced the assurance of saving grace which was his comfort and support in later life. But we can imagine how men accustomed to the lax religion of the time, administered by an ignorant and careless clergy—for such they were—must have been affected by the greatest revival that has ever taken place, to which Wesley and the Salvation Army are but ripples on a pond to a storm in the ocean, and what, to men living under the formalism of Rome, must have seemed the splendour of Calvin's great announcement that the creature could commune with the Creator, that the individual soul could approach the Divinity, that there was no barrier between God and man. Men's minds are naturally fascinated by horrors. Gloomy creeds have created the fiercest enthusiasm, and the Independents, the logical sons of Calvin, though he would have been the first to disown them, formed the most remarkable army that England has ever raised.

But if we find it hard to understand the acceptance of Calvinism, still harder is it to comprehend a society in which toleration was not only not approved, but was even abhorred as treachery to God. The Puritans were mocked as saints, but they spoke of themselves by the same term, and it was not always undeserved. Some of them were as truly saints as any that religion ever had. But even such men hated their opponents with a violence we can hardly believe, and had no thought of allowing them any kind of toleration. Calvinist, Arminian, Anglican, Independent, and Papist, each was convinced that his own opinion was the true, and each was determined that it should be enforced on every man, woman, and child in the country.

Posterity has undoubtedly approved the political aims of the Long Parliament, and looks upon it rightly as the preserver of English liberty. We are therefore the more astonished to observe the complete dearth of constructive political ability which marks its ranks. They pulled down everything; they built nothing. The Calvinists destroyed the Church; the Independents destroyed the Commons, the Lords, and the monarchy, and they themselves, when they turned out the Rump and set up the

Protectorate, were attacked by the Republicans and Fifth Monarchy men, who plotted the assassination of Cromwell. Compare what Cromwell, honestly anxious to restore good government, could do for England in the years of his power, with the complete system of administration—religious, educational, judicial, municipal, and financial—which Napoleon established between 1800 and 1811; or, if you like a modern instance, with the system of government established in Italy since the war. It may be that when Mussolini dies the edifice will fall; but see what force and what creative imagination he has displayed.

The great vice of the age was its intolerance, and the religious mania, for we can call it nothing else, which overran England between 1560 and 1660 like an epidemic, did not even, like bodily epidemics, leave a population behind it immune to its particular poison. Never was religious hatred more bitter than after the Restoration, and in its graver forms it persisted for over a century and a half. Catholic emancipation was not carried till 1829. Oxford and Cambridge were not thrown open till 1871, and mutual respect and good will between the Free and the Established Churches is a growth of the last thirty or forty years.

It has been claimed that the Puritans preserved the family life of England from the corruption and the licentiousness of court manners. Such statements assume, on the one hand, that the court society of the day was something exceptional, and on the other that the manners of the capital were the manners of the country. Neither is true. It is said, too, that to the Puritans we owe that sturdiness which has kept and increased the liberty they won. Neither is this to be accepted. Lived there no brave men before Agamemnon? Did not the men of that day expressly proclaim themselves followers in their fathers' footsteps, guardians of what they had obtained by peril of their lives? The temper of a great nation is a thing too firmly set to change under every blast of new doctrine, and its history is the consequence of its character, not the cause of it. The Puritans were the guardians of spiritual fervour at a season when religion had become cold and dead. Such seasons of decay occur from time to time, and the Puritans are neither the first nor the last of the revivalists. Whenever need arises such men have a great part cast for them on the world's theatre, and none of us should criticize them so harshly as to refuse them their due praise. But we owe to them the loss of half the beauty of England.

But, after all, our interest is not to praise or blame the actors in this great tragedy. It is to consider what was Harvey's attitude to the great struggles, political and religious, that were taking place around him. And of this we obtain from himself no evidence whatever. He mentions the King and Queen two or three times in the *De Generatione*, but without any word either of affection or regret, which indeed in 1651 it might not have been prudent to print. He mentions Parliament once, complaining that the mob had destroyed his collections, though he was attending the King with the permission, and even at the command, of Parliament. There remains only the message that he is said to have sent to Scarborough, who was an ardent Royalist, "Leave thy gunning and come here and I will bring thee into practice." But that may be significant. We may well believe that he would not approve either the folly and tyranny of Charles or the violence and malice of his foes. To Harvey the war must have seemed a vast catastrophe, for which both parties were alike responsible, from which little good was gained, and by which the progress of knowledge was irreparably hindered.

And for religion. No man of serious character then doubted the fundamental beliefs of Christianity, and Harvey was of a reverent mind. But we cannot fancy his sympathizing either with Laud's formal discipline or with the brutal irreverence of the Puritans. Harvey's religious feelings, we may be sure, were too sincere and too deeply felt ever to be published to the world. Addison once asked Garth of what religion he was. Garth replied, "Wise men all hold the same religion." "What is that?" said Addison, and Garth answered, "Wise men never tell."

TREATMENT OF BURNS AND SCALDS.

THE TANNIC ACID METHOD.

It can hardly be doubted that one of the most important recent advances in modern therapeutics is the introduction of tannic acid for the treatment of burns and scalds. In 1925 Dr. E. C. Davidson of Detroit contributed a carefully argued paper on this subject to the August issue of *Surgery, Gynecology and Obstetrics*, the salient points of which were detailed in our *Epitome* of September 12th, 1925 (para. 185). Davidson advocated the use of gauze dressings saturated with a 2.5 per cent. freshly made aqueous solution of tannic acid, with a view to coagulating the damaged tissues and so preventing the absorption of toxins. He added that the subsequent formation of scar tissue was found to be notably less than when other methods of treatment were employed. Various investigators in Great Britain subsequently made trial of the method, but their reports were not always favourable.

At the Annual Meeting of the British Medical Association in Edinburgh in 1927, Mr. W. C. Wilson, assistant surgeon to the Royal Edinburgh Hospital for Sick Children, reported a series of thirty-seven cases of burns in children *treated by tannic acid* (*British Medical Journal*, 1927, vol. ii, p. 591). His method consisted in the spraying over the burnt tissues of a 2.5 per cent. solution of tannic acid at intervals of an hour, the surface being dried by electrical heat. The highly gratifying results obtained encouraged Mr. Wilson to continue his investigation, in the Department of Surgery at Edinburgh University, and a report by him was published in our columns on July 21st, 1928 (p. 91), in which certain important principles were enunciated and the results of treatment were recorded in forty-two infants and eight adults. The attention of the Medical Research Council having been drawn to the method, it was observed that the procedure was not so popular in hospitals as might have been expected, and that the results reported did not appear to be uniformly good. The Council therefore invited Mr. W. C. Wilson to make a further survey of his results; and a memorandum by him has now been published as No. 141 of the Special Report Series of the Medical Research Council, which may be obtained from the Stationery Office, price 1s.

Clinical Course and Pathology of Burns.

Mr. Wilson adheres to the view expressed in his article in the *British Medical Journal* that the customary classification of the clinical course of burns into the three stages of shock, inflammation, and healing is misleading. He recognizes and defines carefully four stages—namely: (1) shock (initial or primary); (2) acute toxaemia (secondary or toxic shock); (3) septic toxaemia; and (4) healing. It is admitted that there are wide variations in the duration and importance of these stages, depending on the extent and severity of the injury, and, more especially at the present time, on the treatment adopted. The second stage in the past was unquestionably regarded as the most important, and showed the highest mortality. The first two stages were described by Mr. Wilson in his article in these columns, and need not be considered further here. As regards the third stage of septic toxaemia, Mr. Wilson remarks that its symptoms and signs may be evident from the fifth day until healing is advanced. Clinically it may be absent, or, conversely, the bacterial infection may be so severe as to cause acute toxaemia and death; the pathological condition is, as he remarks, that of an open wound, and some degree of infection is always present when any considerable area of epithelium has been destroyed. The fourth stage—that of healing—begins when the infection has been overcome; its duration depends largely upon the depth of the lesion. First and second degree burns heal quickly and without formation of scar tissue, whereas in third degree lesions the granulating surface becomes covered with epithelium derived partly from the edges and partly from epithelial islets which have escaped destruction. In still more deeply burned areas healing is slow, and, owing to the tendency of the scar tissue to contract, deformities and disability may follow.

Treatment by Tannic Acid.

Mr. Wilson's method has already been described in detail in our columns, but it may be recalled that he sprays over the burned areas a warm, freshly prepared solution of tannic acid from an ordinary nasal spray atomizer, the parts being then dried by means of electric lamp bulbs in a bed cage. The spraying and drying are repeated at frequent intervals until all the burnt area is covered by a thin layer of brown coagulated tissue. He now adds, that, although a 5 per cent. tannic acid solution has been recommended by some authorities, it has, in his opinion, no special advantage over the weaker solution, while very strong solutions have a corrosive action. In burns of the face, he adds, coagulation of the cornea is an accident to be guarded against; the eyes, nostrils, and external auditory meatus are protected by moist wool during the spraying process.

Summary of Cases.

In the report under notice details are given of 117 cases so treated; in ninety-five of these the injury resulted from scalding, and in twenty-two from burning by fire. All except twelve patients were children below the age of 10, and eighteen were less than 1 year old. The death rate in the series was 11.1 per cent., which must, as Mr. Wilson remarks, be regarded as extremely satisfactory; even though cases of less extensive burns are more frequently admitted to hospital now than formerly, there can be no doubt that the mortality has been reduced in a most striking manner by the introduction of tannic acid. With previous methods of treatment shock accounted for 2.5 per cent. of the deaths, acute toxaemia for 80 per cent., and sepsis for 15 per cent., the remainder occurring from causes unconnected with the injury. In the present series 30.77 per cent. of the deaths were due to shock, 23.77 per cent. to acute toxaemia, and 23.77 per cent. to sepsis. In other words, the second stage is no longer the main danger period; the acute toxaemia, which was the chief cause of the high mortality in the past, can now be controlled; it is rarely prominent and never occurs in a fulminating form. The mortality in 105 children under the age of 10 was 10.5 per cent., as compared with 38.7 per cent. in a series of comparable cases treated by other methods; the prognosis has also improved. The outlook in children is considered favourable now when the involvement of total body surface is less than 35 per cent.; though serious, it is not hopeless even if as much as 60 per cent. of the entire surface of the body is affected; burns of still greater extent than this prove rapidly fatal. Mr. Wilson supplies clinical details of four cases, and illustrations showing the rapid healing by the tannic acid method. He adds that it promotes rapid analgesia, there being no pain or discomfort while the coagulum is present; healing is usually rapid, and contractures as a sequel are exceptional.

Practical Application of the Method.

Mr. Wilson advised, in his paper published in this *Journal* on July 21st, 1928, that tannic acid should form part of the armamentarium of the country practitioner, and find a place in the first-aid equipment in mines and factories. Packets containing 110 grains of the powder can, he suggests, be kept ready for emergencies; one of these dissolved in half a pint of water provides the necessary 2.5 per cent. solution. In the report under review an appendix contains provisional instructions for applying the treatment under first-aid conditions. His original suggestions have been improved in some respects as the result of helpful criticisms and suggestions proffered by the medical inspector of mines and the professors of surgery at St. Thomas's Hospital and University College Hospital.

It is suggested that in mines and other places where burning injuries are not uncommon the emergency first-aid treatment might take the following lines. A first-aid "*unit*," which is kept ready, consists of two two-pint enamel measures graduated in ounces; two glass rods; fifty packets of tannic acid powder, each containing 110 grains; a bottle containing tablets of corrosive sublimate, each of 8.75 grains; twelve rolls of white absorbent wool; eight dozen gauze bandages; a jar of vaseline, and a flat stick for its application; and five dozen packages of sterilized white lint, each package consisting of a piece of lint covered by a layer of gauze and wrapped in Kraft paper. The lint is in three forms: (1) a piece measuring 20 by 30 inches, this package being labelled "*trunk*"; (2) a bandage 4½ inches by 3 yards, labelled "*bandage*"; (3) a face-mask measuring 1 by 2 feet, in which are cut the following openings: one of 7 by 1½ inches to expose the eyes, and two horizontal slits of 3 inches and 3½ inches long as openings for the nose and mouth; the package is labelled "face." The instructions in the case of a burn occurring are as follows. Remove all clothing from the burned area in order to estimate its dimensions, but prevent the patient becoming chilled; no cleansing is to be attempted. Prepare the tannic acid solution by dissolving in two pints of water one tablet of corrosive sublimate and four packets of tannic acid powder, stirring with the glass rod until all the powder is dissolved. The solution is antiseptic, and there is no need to sterilize measures, glass rods, or powder. It must be warm when applied, so as not to cause chilling of the patient. The lint in the "trunk" package will cover the entire front or back, and requires one pint of solution. The lint in a package labelled "bandage" will cover one arm entirely, and requires half a pint of solution. Two "bandages" cover one entire leg, and use up one pint of solution. The piece in the "face" package will cover the face, neck, and sides of the head, and requires six ounces of the solution. According to the surface extent and regional distribution of the burns, a suitable number and type of packages are selected. The lint is soaked in the solution and wrung out gently, and its smooth side is applied to the burned area, after which it is covered with a layer of wool and fixed with a gauze bandage. The hands should be washed thoroughly with soap and water before the lint is touched. In the case of burns of the face the patient is told to keep his eyes closed while a thick layer of vaseline is smeared over the eyelids, eyebrows, and for some distance round the eyes; the vaseline area should be covered by wool. The face-mask is soaked in the solution and wrung out firmly; it is then applied to the face, leaving the regions of the eyes, nostrils, and mouth exposed through the slit openings in the lint. It is held secure by a gauze bandage round the head and neck, the openings being widened if necessary.

The packages with the covering of Kraft paper are previously sterilized by steam for twenty minutes at a pressure of 15 lbs. and then dried; the lint will remain sterile for a long period if the packages are kept clean and dry. The whole "unit" is placed in a wooden box and stored in a dry place. The powder packets are best kept in a tin box with a tightly fitting lid.

Mr. Wilson is certainly to be congratulated on the success that has followed his persistent efforts to establish the full value of a most useful remedy, and on his careful study of all the scientific principles involved. In a preface to his report, contributed by the Medical Research Council, it is pointed out that his work raises scientific questions of considerable interest, and that still further investigation is desirable based on the discovery that tannic acid has this undoubted power to diminish or abolish the dangerous secondary shock or acute toxaemia following burns and scalds.

GUIDING PRINCIPLES OF PUBLIC HEALTH REFORM.

PRESIDENTIAL ADDRESS TO THE SOCIETY OF MEDICAL OFFICERS OF HEALTH.

THE annual general meeting of the Society of Medical Officers of Health was held on October 25th, when DR. JOHN J. BUCHAN, medical officer of health for Bradford, was elected and installed as president of the society.

In an address from the chair on "Some principles of public health reform," Dr. Buchan said that public health was a practical application of scientific knowledge; in this country full use was by no means made of the knowledge already gained, and there was a still greater lack of facilities for investigation and research whereby this knowledge might be increased. The possibilities of success in health work were limited only by the boundaries of knowledge. Just as manufacturers maintained research workers and institutes of various kinds to assist them in their respective industries, so the State might well do something more than leave the great bulk of research work in health and medicine to the self-sacrificing labours of a few or the vicarious generosity of the well-intentioned. Furthermore, any great advance in the application of knowledge required a constant revision and readaptation of organization, both central and local. In public health work

in England this was a task of no small difficulty, because the subject had been developed, not on any systematic and well-ordered plan, but as a result of sporadic activity in different fields. Social reformers had drawn attention to the special health needs of some particular class which appealed to them at the time, and piecemeal legislation was the result. No doubt such legislation served a temporary purpose, but ultimately overlapping, inefficiency, and waste occurred. One of the great tasks of the Ministry of Health had been to bring order out of the chaos into which public health work had been plunged owing to a century of patchwork legislation. This work had not been completed, but substantial progress had been made since the creation of the Ministry, and the general lines of reform were beginning to be disclosed.

Public Health an End in Itself.

Certain principles must be steadily adhered to if this work was to reach a successful issue. The first laid down by Dr. Buchan was that the protection and improvement of the health of the people should be regarded by the State as an end worthy to be sought by itself. A large amount of work in the past had been badly done because it was undertaken to serve some other purpose. An outstanding illustration, shortly to cease, was health work under the Poor Law, which had been done, not to meet a health need, but for the relief of destitution. Another example was factory legislation, in which health considerations were approached primarily from the point of view of certain trades and industries, without full regard to the more important question that good conditions of health should be enjoyed in all employment. It was true that certain inimical conditions were peculiarly liable to arise in some industries, but these were not confined to the industries to which factory legislation had been made to apply. In the result, despite a succession of statutes and a multitude of orders, factory legislation had failed to meet fully the real health needs of the whole body of employed persons. Health and labour conditions were, of course, closely interwoven, but Dr. Buchan refused to regard the health of the worker as a labour problem to be solved by the codification of industrial laws. Whatever reform was imminent, it should bring the health of employed persons within the survey of the Ministry of Health, not leave it in the hands of the Home Office.

Integration of all Branches of Health Work.

A further principle in public health was the close integration of all classes and conditions in the community. Bad health conditions in one class of society or among individuals related by one set of circumstances had comparable results in very different quarters. To combat ill health, for example, at one age, required, more often than not, action at quite another age. It was not possible to sectionalize the population. Take the case of the expectant mother. Here were special conditions arising in a particular class of the community. But health in pregnancy had a most profound effect on the health of the nation, and no proper consideration of the matter could be made unless it were viewed in relationship, not only to the expectancy, but also to the conditions before expectancy, and those liable to arise afterwards. Take, again, the school child. There was no disease or condition of ill health which could now be associated with school life alone, and few, if any, conditions of ill health amongst school children the prevention and cure of which were to be sought in the educational system. The more closely the conditions of health of school children were inquired into, the further was the inquirer taken from the school. The school was little more, from this point of view, than a convenient centre in which children might be surveyed and teachers instructed on health matters. Tonsils and adenoids, mental defect, defective vision, even dirty and verminous heads, were in essence hardly problems of school life at all.

Reorganization at the Periphery.

The third principle of public health reform remarked by Dr. Buchan was that central unification and reorganization of health effort was not in itself sufficient unless accompanied by a similar unification and reorganization at the points of actual administration. The passing of the Local Government Act, 1929, was the first step towards this end, but, sooner or later, legislation would be required to unify health services locally. At present this was being done chiefly through the influence of the Ministry of Health, but local circumstances existed in many places where it could not reasonably be required. Health work generally in this country had from the start suffered from the want of well-ordered and arranged local government areas. It was incumbent upon the State to see that its machinery was competent in every fashion to discharge the work placed upon it, and the State should not permit any consideration of local history, pride, prejudice, or precedent to stand in its way.

Independence of the Professional Officer.

Finally, Dr. Buchan insisted that the professional officer in health work must have freedom of expression of opinion within his own sphere; not that he sought to control and direct any organization or department set up for a different, though allied, purpose, but in giving advice he must have a free right to set forth his own opinion on matters of health, whether it be on lead poisoning among painters or the exclusion of school contacts in infectious disease. Dr. Buchan concluded his thoughtful address by quoting Carlyle: "Health is a great matter both to the possessor of it and to others. . . . Does not health mean harmony, the synonym of all that is true justly ordered good; is it not in some sense the net total . . . of whatever worth is in us?"

Scotland.

University of Edinburgh.

Sir Thomas Henry Holland, F.R.S., the new principal of the University of Edinburgh, was formally welcomed by the students on October 25th at a luncheon in the University Union, Edinburgh. The new principal, in replying to his toast, said that he would like to express one thought sincerely and seriously to the senior men who were able to advise the juniors. He considered that the man who went out from the University with a degree was not of the slightest use as a citizen of the world unless he had taken his share in the students' social and athletic activities. The student had to determine how much of his life was to be devoted to social activity and how much to academic work, and if he over-did one or other he was bound to suffer, and he hoped that students would keep a clear balance between the requirements of social life and the absolute necessities of academic work.

For the first time in the history of the General Council of the University of Edinburgh the Lord Rector (Sir John Gilmour, M.P.) presided at a statutory meeting of that body, on October 25th. A cordial welcome was extended by the council to the new principal, Sir Thomas Holland. Dr. Alexander Morgan, convener of the Business Committee, referred to the statistics in the last report of the Treasury Committee on University grants, which showed that two-thirds of the total increase of students in the United Kingdom had taken place in the four Scottish universities. Of the British universities, Edinburgh attracted most students from the Empire overseas and from foreign countries, the total being 650. Cambridge came next with 637.

Principal Sir Thomas Holland presided, on October 25th, at the opening ceremony of Cowan House. This is a new residential hall for students attending the University of Edinburgh, situated in George Square, and accommodating about one hundred students. It is the gift to the University of Dr. Thomas Cowan, a well-known Scottish shipowner. The large hall and house were declared open by Sir John Gilmour, who expressed the gratitude of the University to Dr. Cowan, the donor. Dr. Cowan, in replying, said that if the establishment tended to awaken the social life of the University and to bring the colonial student into a happy community, he had an ample reward. He trusted that the home atmosphere of the house would make the latter feel that he was not far from home, despite the element of distance, and that students from the Scottish glens and sons of empires from across the seas would there form friendships which would remind them in after years of happy connexions with the city of Edinburgh and its great University.

Extension to Sick Children's Hospital, Edinburgh.

A ward for the treatment of ear and throat diseases in children was opened at the Royal Edinburgh Hospital for Sick Children on October 22nd. Mr. Colin M. Black, chairman of the hospital, performed the opening ceremony, and said that this hospital was in the present instance showing the way towards an advance, for, so far as he was aware, no other children's hospital in the country possessed a ward set aside exclusively for such cases. Owing to the special importance of such disorders in children, and the great increase in the number of patients with complaints of ear and throat attending the hospital, a special department had been formed a year or two before the war under the charge of Dr. Porter. After his death in the war, Dr. Douglas Guthrie had been appointed to succeed him in 1919. At first only two beds had been reserved for ear and throat cases, the number being afterwards increased to five, but as the directors found that, owing to lack of accommodation, many children had to be treated as out-patients who would have been better in a ward, the present extension of the hospital had been instituted. The number of new patients attending the ear and throat department had risen from 767 in 1920 to over 1,200 in 1928, and he believed that in the present year there would be considerably over 2,000. Of these, it had only been possible to admit as in-patients some 300. This ward, with 12 beds, which bring the total number of beds in the hospital up to 132, has been named the Meikleham Ward in tribute to the memory of a benefactor of the hospital.

Reception to Glasgow Medical Graduands.

In accordance with the now well-established custom, the council of the Glasgow and West of Scotland Branch of the British Medical Association entertained the successful students at the recent final medical examination at Glasgow University at an "At Home" in the Men's Union, the University, on October 17th, the day before the graduation ceremony in the Bute Hall. The atmosphere of the meeting was distinctly homelike, and the students were obviously well disposed to the British Medical Association. After tea and general conversation, Dr. G. Morris Crawford (Uddingston), President of the Branch, took the chair, and called upon Professor Ralph Stockman to address the students. Professor Stockman, in a characteristically witty speech, said that on the following day, as the University was at present in the position of having no vice-chancellor and principal, the duty of capping the students would fall to himself, and as he understood that he was not to be allowed to make them a speech on that occasion, he was very glad to have that opportunity of wishing them God-speed. No doubt there were among them some who had come down in several examinations, but he instanced the names of several famous men who had not shown the evidence of any special talents during their earlier years. Again, no doubt, there were others amongst them who had been more or less distinguished students, and again history abounded in the names of famous men who *had* had notable university careers. There was therefore no need for the second group to be any more discouraged than the first. He advised as many as possible of his hearers to obtain a resident hospital post for however short a time before they went into practice. A voyage to the East, and even a few short weeks living in London were a liberal education. As to the British Medical Association, it would not be very long before they heard a considerable amount of criticism of it, but they would hear that about almost everything, and no doubt they had already heard criticism of himself. The point was, however, that the B.M.A., like most other things that were subject to criticism, was the best they had. Dr. J. R. Drever (Scottish Medical Secretary) gave a brief outline of the work of the Association and the advantages to newly qualified graduates in becoming members of it. Dr. Towart of the Medical and Dental Defence Union of Scotland was also given the opportunity of explaining the imperative necessity of joining a medical protection society. At the end of the meeting fifty-three students signed application forms for membership of the British Medical Association, and next day a further twenty-five forms were duly signed.

Lewis Hospital.

Considerable discussion has recently taken place in connexion with a decision by the managers of the Lewis Hospital to terminate the engagement with Mr. J. Ewart Purves, F.R.C.S., as surgeon-superintendent of the institution. The Lewis Hospital is one of the surgical units established under a scheme designed by the Department of Health for Scotland in order to bring to remote areas, such as the Island of Lewis, the benefits of modern surgery. The scheme took form in 1924, when, as an experiment, a medical superintendent and surgical consultant was appointed for a period of five years. Since then the institution has been extended and modernized at a cost of £12,000, defrayed by the Department of Health, who also paid the salary of the surgeon-superintendent. The maintenance of the institution otherwise is defrayed by the management of the hospital, largely from voluntary subscriptions. Details of the improved scheme appeared in the *Journal* on May 12th, 1928 (p. 821). A strong protest from the medical profession in the Island of Lewis was lodged with the managers of the hospital against their refusal to enter into a new agreement with the present surgeon-superintendent, and a deputation from the Department of Health, consisting of Dr. Parlane Kinloch and three other members, went to Stornoway to investigate the working of the Department's experimental scheme. On October 25th a conference was held between these representatives and the local authority of Lewis, in connexion with the whole medical, nursing, and hospital services of the island. Dr. Kinloch presided, and said that since 1913 there had been developed in the Island of Lewis a medical and nursing service of a very high order, and to make this scheme complete the Department of Health and the managers of the Lewis Hospital had, in 1924, entered into an agreement to provide a modern institution and a specialist surgical service. The Lewis Hospital was now one of the best surgical units in the North of Scotland, and the surgical, radiological, and nursing services provided at the hospital were of a very high standard. The people of Lewis had rapidly realized the value of these services, with the result that full advantage was being taken of them, and transport facilities to the hospital were improving. He added that the present arrangement between the hospital managers and the Department of Health would continue, and he paid a high tribute to the surgical skill and devoted service of Mr. Purves, the surgical specialist.

Fitness among the General Population.

Colonel P. S. Lelean, professor of public health in the University of Edinburgh, in the inaugural address of the Combe Trust series of lectures on public health, emphasized the vital importance of national fitness in the strenuous competition of the world's markets, and gave figures which showed the extent of ill health prevailing in this country at the present time. He estimated that sickness, sufficient to incapacitate from work for over three days, keeps an average of 190,000 persons away from work throughout the year in Scotland alone, and causes an average of fifteen days' lost work per worker per year. The sum lost to the nation in this way amounted to £31,461,000. Expressed otherwise, he calculated that among 100 average people doing their usual work, there were 14 definitely sick and 35 others unfit to an extent which prevented their maintaining their full efficiency. The lecturer pointed out that if these figures for Scotland were applicable to the rest of the country, then it might be concluded that the loss due to sickness in Great Britain amounted to £283,000,000 annually, or about the same as the total interest upon the national debt. Sickness was therefore really a more pressing matter than unemployment, both on account of its greater magnitude of cost and misery, and because an immediate reduction might be made in its amount by healthy living. Every sick worker lessened the nation's output, raised sale prices, reduced overseas trade, added to unemployment, and raised the price of food, all in inevitable sequence. With regard to remedial action, the lecturer considered that the public had lagged behind doctors in the matter of what they ought to know regarding the maintenance of health. It was the first duty of the educationist

to teach the art of keeping fit. Health was now recognized to be something more than the mere dodging of disease and delaying of death; it was the art of getting out of oneself and of life the very best, and of being all the time on the 100 per cent. line. What could be achieved was illustrated by the experience of the army. In the army of 1855 the death rate was nearly double (185 to 100) that for civilian males of military age; about the year 1900 the two rates drew level; but when every private in the army was instructed in sanitation its death rate fell to three-quarters that of the civil population by 1910. The army had thus led the way for brilliant results, and when the elements of hygiene were taught to every child in our schools the lecturer believed that as striking an improvement would occur in the health of the nation. He hoped that the additional year of school life would be wisely utilized for some such purpose.

Ireland.

Radiotherapy in Ireland.

On October 19th, at the opening meeting of the fifty-fifth session of the Dublin University Biological Association, Professor J. Brontë Gatenby delivered his inaugural address, taking as his subject "Radium, x rays, and the cell." Dr. Madill, outgoing president, occupied the chair. Lantern slides were used to illustrate the subject-matter of the address.

Professor Gatenby's Address.

Professor Gatenby, having expressed his appreciation of the honour of having been invited to become president of the association, said that the subject of his paper was an apt one in Trinity College, for the pioneers of x radiation in Ireland were the late Dr. Lane-Joynt and Dr. W. S. Houghton. The association was much honoured that night by the presence of Dr. Joly and Dr. Stevenson. Dr. Joly, in conjunction with Dr. Stevenson, worked out the method of placing radon, or radium, enclosed in needles, around and in a tumour. This brilliant discovery was now being used all over the world, especially for cancer of the tongue. He was glad to welcome Dr. R. Ludford of the Imperial Cancer Fund Laboratory, London, and Fouterton Scholar of the Royal Society of London. Proceeding to the subject of his address, Professor Gatenby reminded his audience that it had been known for over a quarter of a century that rapidly growing tissues were deleteriously affected by the rays given off from x-ray tubes and from radium. Thus skin, gonads, mucous membranes, and blood-forming tissues were all easily damaged by exposure to x or radium radiation. A characteristic of cancer cells was that the inhibition of cell division was either poor or absent. It was common knowledge that the erratic course of cell division followed by cancer cells could be checked by radiation. The tumour usually recurred, however, in the same position or in metastases. The rapidly growing type of tumour responded best to radiation; the less active types were difficult to treat properly. The question of radiosensitivity was all-important in the treatment of growths. Broadly speaking, the growing cell was the more radiosensitive, and theoretically, by striking a dosage which would incommode the growing cell and would not deleteriously affect the resting cell, one could hope to eradicate, or at least arrest, cells with a rapid division rate. In practice, radiation might have only a temporary effect. Only a proportion of the undesirable cells might be dividing or rapidly growing, and so expose themselves to destruction; likewise, the division rate of the growing cells might approximate to that of the cells of the normal tissues, so that it was difficult, if not quite impossible, to hit off the proper dosage. Having referred to several classes of material which had been generally used for x-ray research, and to experiments on the effect of radiation on cells, the speaker said that the great advantage of the tissue culture technique was that, no matter what might be the actual structure of the cell, cell multiplication went on; it might be watched, and the number of cell divisions accurately counted. No other type of material offered such a good opportunity for watching the effects of radiation on the numbers of cell divisions, and therefore on growth itself.

The appearance of warts on the hands, wrists, and sometimes faces of working radiologists was common. X-ray dermatitis, which after many years might be followed by epithelioma, was not now so common as it used to be. The wart was evidence that the skin cells had begun to divide very rapidly in one situation. The rapid growth might usually be controlled by treatment, but the appearance of an epithelioma showed that small doses of x rays over a long period could cause a pernicious growth. The appearance of warts on the hand seemed a negation of the rule that irradiation killed actively growing cells; it might, in fact, be interpreted as evidence of a stimulating effect. This example had always struck him as one of the most difficult to interpret on the assumption that x radiation did not stimulate. The x ray might be supposed to have deprived the skin cells of their division inhibition; but there seemed no escape from the conclusion that the end effect was a stimulation, if by stimulation one meant a rapid accession of cell divisions in parts exposed to radiation. The question of possible stimulation by radiation was of prime importance, but very confused and difficult, said the speaker, who went on to review what might be called the laboratory evidence for stimulation, and stated that all the cytological evidence was against the view that radiation stimulated the cell. X-ray dermatitis was practically always found only in radiologists who had been years at their work. In the current laboratory experiments to test stimulation, exposure was over only a very short period, and exposure of tumours to x rays or radium was also only for short periods. It seemed clear, therefore, that it was unfair to class x-ray dermatitis as evidence for stimulation in the sense that the word was used by radiologists and by him in his address. Professor Gatenby mentioned that, in answer to a letter he had sent to the National Radium Commission it was stated that this Commission did not extend to the Irish Free State.

General Discussion.

Professor Joly moved that the best thanks of the University Biological Association be accorded to the president, Dr. Gatenby, for his valuable address. He said his excuse for speaking lay in the fact that the several domains of science were not shut up in watertight compartments. Roughly speaking, the therapeutic use of radium began very tentatively in or about the beginning of the present century. As one of the governors of Dr. Steevens's Hospital, he then witnessed the cure of a case of rodent ulcer by the application of a little radium which he had obtained from Germany. In subsequent years a number of modes of radium application were introduced, but all were objectionable for one reason or another. With the formation of the Radium Institute of the Royal Society, Dublin, in 1920 a new technique, involving the use of hollow needles, was employed. The chief advantage of this technique was in the uniformity of radiation thereby secured. The Radium Institute was from the first a great success—largely, owing to Mr. Richard Moss's skill in overcoming the technical difficulties attending the separation of the radium emanation and its introduction into the capillary glass tubes destined for insertion in the hollow needles. The most important event in its subsequent history was undoubtedly the obtaining of a loan of 220 milligrams of radium from the British Government in 1920. He was glad to say that Dr. Stevenson's priority respecting the introduction of the needle technique was freely recognized in a very important paper by James Ewing of the Memorial Hospital, New York, and that the method had been standardized in the Radium Institute of the University of Paris. A recent addition to the needle technique was the introduction of hollow needles which would emit radiations of very differing strengths from opposite sides of the needle. These needles were, in fact, bi-radiant, and their use would be valuable where it was desirable to radiate a tumour uniformly to its very margin, without unduly

radiating the surrounding tissues; he had been told that these conditions applied more especially to cerebral tumours. He cordially welcomed Dr. Gatenby's reference to the necessity of obtaining radium for purposes of research; he issued a warning, however, against the danger of dividing their forces. That each hospital should possess its own supply of radium was a policy of perfection; but it was one which, even if attainable, was sure to prove wasteful, for the reason that the radium must often be laid by doing nothing. To deal locally with its emanation would involve a running expense quite beyond the reach of any of their hospitals. This great expense was borne by the Royal Dublin Society, where the work was carried out under conditions involving the constant care of an experienced scientific officer, and securing absolutely reliable data as to the strength of the dosage. He would ask the boards of hospitals to hold their hands until they could combine with a view to providing their Radium Institute with a supply of radium adequate to meet the demands of research as well as of routine treatment.

Dr. Walter C. Stevenson said that between 1914 and the end of last year he had treated with beta and gamma rays, given off during the disruption of radium B, and more particularly radium C, 2,143 patients, and had records of the doses and technique employed in practically every case; this year he had treated 215 cases, making a total of 2,358. Of these, 531 were for gunshot wounds and other injuries received during the great war, this treatment having been approved by the War Office after his results had been investigated by Sir Robert Jones and his colleagues at Liverpool. When body cells were unable satisfactorily to cope with infection or disease, mild radiation had a pronounced effect, and was able to influence the tide of battle for the benefit of the patient. In regard to inoperative cancer, he said that if the case was far advanced radiation could be considered only as a palliative measure, because it was futile to cure cancer and kill the patient. Skin cancers and rodent ulcers were very amenable to radiation. Dr. Stevenson went on to speak of the treatment of non-malignant conditions where long-continued, very gentle radiation had proved most beneficial in influencing the course of chronic ailments and infections, and gave figures representing the number of cases treated to illustrate the opinion that his colleagues and others entertained of this treatment.

Professor Maurice R. J. Hayes, who proposed the motion that the Dublin University Biological Association was worthy of the support of all students of medicine and other sciences in that University, said that radiotherapy was no longer empirical; it was now an exact science. Radiation was, however, a very potent and, therefore, a very dangerous therapeutic agent. One of the essentials of therapeutics was an accurate knowledge of the quality, the dose, and the effects of the remedies they employed. A great many variables must be considered, and inattention to their control could end only in failure or disaster. Sir William I. de C. Wheeler, in seconding the resolution, said that in the Biological Association the spirit was good and the outlook was wide. He carried with him many impressions left from his apprenticeship to the association as secretary, and afterwards as president, in the old days. They were taught as students a sympathetic respect for advancing thought; they were made to realize that in a progressive science, such as medicine, books and rules and time-honoured doctrines must pass and fail, and by coming in contact with distinguished visitors and contributors they learned to honour the wisdom of the cultured mind. Everything in the State depended upon an efficient medical service, and the birthplaces of efficiency were associations such as he was addressing that night. Dr. Leonard Abrahamson and Dr. Reginald Ludford supported the motion, which was passed. Dr. Madill, in acknowledging a vote of thanks, endorsed the remarks of some of the previous speakers about the therapeutic value of radium, especially in diseases of women. It was a method of treatment full of promise, and one in which he took a great interest; he hoped something would be done very soon to provide the Dublin hospitals with a supply of radium adequate to their needs.

England and Wales.

Infantile Mortality in Kensington.

AN attempt is being made in Kensington to intensify the campaign against infant mortality and to co-ordinate the activities of general practitioners and the public health service to this end. The North Kensington Medical Society, which is composed of medical practitioners in the district, and meets monthly, arranged a meeting last summer of local practitioners and the medical staffs of the Kensington infant welfare centres, with a view to fuller co-operation. More recently, the society held a meeting on October 8th to discuss the high mortality rate in the borough for 1928; there were present as guests members of the executive committees of the Kensington and Chelsea Divisions of the British Medical Association. A circular issued in connexion with this meeting called attention to the fact that the infantile death rate in Kensington had considerably increased in the last three years, and was very high as compared with that in neighbouring boroughs. Certain conditions were cited as being possible factors in favouring infantile mortality and morbidity—namely, unsatisfactory housing conditions in parts of North Kensington; inadequate cleansing of the streets and the removal of house refuse in the same district; and the prevalence of casual employment. The chief suggestion submitted was to the effect that a system of inquiring into all infantile deaths might well be devised, and that the medical officer of health and local practitioners might co-operate in this. In the ensuing discussion no agreement was reached as to any one single cause being concerned; many factors appeared to contribute to the admittedly high death rate. Dr. James Fenton, medical officer of health for Kensington, emphasized the point that the method of allocation of births and deaths among the London boroughs by the Registrar-General increased the figure for Kensington. A resolution was subsequently passed deploring the high infantile death rate and recommending further investigation of the cause of death in all cases when this occurred under the age of 1 year. It was suggested that three members of the North Kensington Medical Society should confer with the medical officer of health with a view to devising such a scheme, or to facilitate further use being made of the existing methods of combating infantile morbidity and mortality.

Rebuilding of the Treloar Cripples' Hospital.

Concurrently with the coming of age of Lord Mayor Treloar Cripples' Hospital and College at Alton in Hampshire, the rebuilding of the institution has been started, and the foundation stone of the new wards was laid on October 22nd. The present hospital buildings are timber structures remaining from the Princess Louise Military Hospital for troops returning from the South African war. The cost of repair and upkeep of the building has reached a figure equal to the interest on the estimated capital outlay for a new building, and therefore the trustees have judged it more economical to rebuild, and thus enable the institution to be more effectively adapted to the care of crippled children. The hospital is to be rebuilt on the same site, and the plans of the architect, Mr. H. C. Smart, are for five ward-blocks, each of sixty beds, all with a southern aspect on a continuous terrace, nearly 1,000 feet long, at the same level. Provision is to be made for sun and open-air treatment, and the wards will have sliding roofs, so that it will not be necessary to wheel the cots out into the sunshine. The rebuilding is expected to cost £100,000, but it will only be completed as finances allow, and the work will be carried out without the closing of a single bed. As the founder of the institution, the late Sir William Treloar, was a distinguished Mason, and 700 lodges have contributed to the funds, it was felt to be appropriate that the stone laying should take place with Masonic ceremonial. The Pro Grand Master of the United Grand Lodge of England (Lord Ampthill) presided over the function, and had the assistance of the brethren in their regalia. The stone was tapped at the four corners

with a mawl used by a workman in Egypt some four thousand years ago, the Pro Grand Master saying, "With temperance, fortitude, prudence, and justice let our work be founded"; and afterwards, from golden vessels, corn, denoting plenty, was scattered on the stone; wine, denoting gladness, and oil, the symbol of charity, were poured; and salt was sprinkled, signifying hospitality and friendship. Sir Henry Gauvain thanked the Pro Grand Master, who, in reply, paid high tribute to the work of the resident medical superintendent and the staff. In the evening a banquet was held in the London Mansion House under the presidency of the Lord Mayor, when Viscount Burnham, in submitting the memory of the founder, mentioned that since the first patients were received in September, 1908, 5,000 children had passed through the institution, 95 per cent. of whom had been successfully treated. At present in the hospital there are 355 crippled children, and fifty crippled boys are being trained in the college.

Municipal Medical and Maternity Institutions in Hull.

Two new municipal institutions were recently opened at Hull. The first of these, the East Hull Clinic, represents an attempt to provide a complete public medical centre, combining the work hitherto carried on at the tuberculosis dispensary in Holderness-Road; ante-natal treatment in Kingston Square; dental, ophthalmic, and massage treatment in Beverley Road; light treatment in Coltman Street; radiography at Cottingham; and the supply of dried milk and nutritive preparations at Hanover Square. By collecting the corporation clinics together the medical officers concerned are now enabled to work in closer association, and team work becomes possible. The new building contains on the ground floor the ante-natal, infant welfare, radiological, orthopaedic, and light clinics, together with rooms for health visitors and food distribution, and a kitchen. On the first floor is a dental clinic with two operating rooms, a waiting room, rooms for medical officers and other members of the staff, and ophthalmic, aural, and minor ailments treatment clinics. The cost of the building has been defrayed by the Maternity and Child Welfare Committee, the contract price being £10,493; the total cost of equipment is estimated at rather over £2,000. The clinics on the first floor are primarily school medical clinics, and so come under the control of the Education Committee, which pays an appropriate rent to the Maternity and Child Welfare Committee. The other institution, which was opened on October 11th, is a maternity home and infants' hospital, situated in Hedon Road. The first maternity home in Hull was provided by Mr. and Mrs. Edwin Robson in 1912, when a house in Holderness Road was equipped as a maternity home for six patients. In 1915 the work had expanded so much that the corporation assumed the responsibility for managing the home; three years later an adjoining house was obtained, thus increasing the accommodation to fourteen beds. From 1924 the work was carried on in a corporation building at Cottingham, and in 1918 the confinements numbered 645. These buildings were required to form part of a new hospital for infectious diseases this year, and arrangements were therefore made for the adaptation of premises in Hedon Road for use as a maternity home and infants' hospital, with accommodation for forty-nine maternity beds, ten isolation beds, eight beds for nursing mothers, and sixteen cots for infants suffering from dietetic diseases. Provision is made for the instruction of twenty-four midwife pupils. It is proposed to close the maternity wards at the Poor Law institutions next April and to undertake all the work now being carried on there in the new maternity home. The corporation is also responsible for a service of municipal midwives, who attend patients in their homes; in 1928 440 women were so visited. All who apply for admission to the maternity home, or for the services of a municipal midwife, attend the corporation clinic for ante-natal supervision. The patients either contribute three guineas a week, or, if they cannot afford this, they are assessed in accordance with an income scale, the usual charge being from £1 to £2 a week. The maternity home consists of six pavilions and an administrative block accommodating a resident medical officer, a matron, and the nursing and domestic staffs. One pavilion is devoted to the treatment of expectant mothers infected with venereal disease. It is hoped that this new institution will suffice permanently for the public maternity needs of the city, and that as increasing use is made of it the maternal mortality and morbidity of Hull will diminish.

Chelsea Clinical Society.

A large number of members with their guests were present at the annual dinner of the Chelsea Clinical Society, which was held at the Hotel Rembrandt on October 22nd. The president, Mr. L. A. Harwood, was in the chair, and among the official guests were the Lord Chief Justice (Lord Hewart); Lieutenant-General H. B. Faweus, Director-General A.M.S.; Sir William Hale-White; and the presidents of the Harveian Society, the Hunterian Society, and the West London Medico-Chirurgical Society. Dr. Halls Dally, who proposed the toast of the "Chelsea Clinical Society," paid a tribute to its president, who, he said, both as a civilian and as brevet-colonel to the City of London Field Ambulance, had shed lustre upon the profession to which he belonged. He appreciated the nicety with which the society, by its practice of combining each of its clinical meetings with an informal dinner party, had succeeded in balancing the two chief aims of a medical society, which were the fostering of high intellectual endeavour, and the promotion of good fellowship. In his reply the president said that the society was in a flourishing condition; the clinical meetings had been well attended, and he believed that the interesting programme for the coming session would attract even larger attendances in the future. On behalf of the members he thanked the officers of the society, whose constant work behind the scenes had contributed so much to its success. Dr. Eckenstein succeeded in weaving into a witty speech graceful reference to the visitors. Lord Hewart began his reply by suggesting that the model after-dinner speech was made by an eminent peer who, many years ago at a whitebait feast at Greenwich, said, "I will follow the excellent example of these excellent little fishes: drink a great deal and say nothing"; fortunately, however, he made no attempt to live up to this standard of post-prandial oratory. General Faweus, who also replied, spoke of the happy relations that exist between the civilian and military branches of the medical profession, and appealed to those who had been members of the Army Medical Services during the war to maintain touch with their old corps.

Correspondence.

A SIMPLE CHEMICAL TEST FOR PREGNANCY.

SIR,—The Zondek-Aschheim test for pregnancy,[1] which consists in the injection of urine into an immature female mouse, has proved to be of considerable service. In practice it has its drawbacks. It requires that a large stock of immature female mice shall always be maintained, and therefore the test is bound to be expensive. It requires also that the specimens shall be sent by post, a procedure that is apt to become a nuisance. Manifestly it would be far better if some test which could be carried out by the practitioner himself, and which did not involve the use of mice, could be devised. An attempt to provide such a test has been made.

In view of the fact that a connexion has been demonstrated between the elaborated products of the pituitary and compounds of the β-iminazolyl type (histamine, histidine, and tethelin), it was thought advisable to test for the presence of such substances in the urine of pregnant women which has been sent here to the pregnancy diagnosis station for examination by the Zondek-Aschheim test.

The chemical method employed was that described by Knoop[2] for the detection of histidine (see also Hunter[3]). 2.5 c.cm. of urine is pipetted into a soft glass test tube (6 in. by 3/4 in.), and 1 c.cm. of bromine water is added.

[1] Zondek and Aschheim: *Die Umschau*, 1928, xxxii, 805.
[2] Knoop: *Beiträge*, 1908, xi, 255.
[3] Hunter: *Biochem. Journ.*, 1922, xvi, 637–9.

This latter consists of one part of bromine water of the ordinary laboratory strength, diluted with twice its volume of tap water. The mixture should be brought to the boiling point, when a positive reaction is indicated by the presence of a pink coloration, which rapidly fades, however. In a negative reaction the original yellow colour is maintained.

It should be noted that the hydrogen-ion concentration of the urine will effect these results, and as changes occur with bacterial contamination, this especially should be avoided. All the urines examined were five to seven days old. If to male, or non-pregnant female, urine a small trace of histidine is added a positive reaction is obtained, whereas the addition of urea, alloxantin, xanthin, alloxan, or arginine to such urine yields a negative result. It would thus appear that the test possesses a certain degree of specificity.

Up to the present 60 urines have been examined, and the results may be tabulated as follows:

Zondek-Aschheim test positive; this test positive ...	24 cases
Zondek-Aschheim test positive; this test negative ...	1 case
Zondek-Aschheim test negative; this test positive ...	2 cases
Zondek-Aschheim test negative; this test negative...	33 cases

The correlation between these two tests has been worked out according to the Pearsonian formula, and χ^2 is shown to possess a value of 48.41, which indicates that a very close relation exists between the findings of these two tests.—I am, etc.,

CECIL I. B. VOGE, B.Sc., Ph.D.

Animal Breeding Research Department,
Edinburgh, Oct. 22nd.

THE CONSTITUTIONAL FACTOR IN EPILEPSY.

SIR,—In his interesting and informative address on the epilepsies (October 26th, p. 745), Dr. Kinnier Wilson includes one paragraph which seems to betray a confusion of thought, or maybe it is only a confusion of expression. In either case it calls for correction. I refer to his paragraph dealing with inheritance, and more particularly to that sentence in which he says: "Twenty-one years of practice and hospital experience have long since convinced me that the hereditary factor is persistently overrated and the personal or constitutional factor underrated." Now this seems to me to contain a direct contradiction, for by "constitution" most physicians and geneticists imply precisely that which is inherited, and the accepted meaning of a "constitutional" disease is one dependent, in part at any rate, upon constitution, or, in other words, upon the germ-plasm. Moxon, writing ten years before Weismann, was, I believe, the first to suggest this as the proper usage for the adjective "constitutional." If we exclude anatomical peculiarities such as supernumerary digits, and physiological defects such as haemophilia, there are few "diseases" which may be said to be inherited in the sense of being both familial and evident from birth and through life. But, in addition to the inheritance of morbid structures and morbid functions, we recognize also the inheritance of morbid dispositions, and of such are those which incline to gout, asthma, and epilepsy. The argument for inheritance as a factor in the development of these disorders is as good as it is in the case of longevity or superior mental ability. Predispositions or diatheses may be considered biologically as variations, and as such may be favourable or unfavourable. In the consummation of a diathesis there is a part played (*a*) by the constitutional or blastogenic factor, and (*b*) by extrinsic or environmental factors. Viewed in this light it is impossible to exclude epilepsy from among the constitutional disorders.

Dr. Kinnier Wilson's epileptic twins supply one of the strongest arguments in favour of the influence of the germ-plasm. The fact that a family history is not obtained in more than 25 or 30 per cent. of all cases of epilepsy (higher figures are given for asthma and gout, but here the expectation of life and fertility is greater) can scarcely, as Dr. Kinnier Wilson seems to suggest, be advanced as an argument against the influence of inheritance. Rather would it be surprising if the figures were higher, when due allowance is made for the influences calculated to dilute existing strains, for inadequate data, and for the circumstance that a certain proportion only of all the victims of a diathesis (or unfavourable variation) meet the determining noxa and develop the disease. As it is, most physicians would, I believe, agree that a positive family history is sufficiently frequent in epilepsy to be helpful in diagnosis.

Perhaps I may appear too particular in asking for a clearer definition in matters of this kind, yet I cannot but think that in medicine, which is a branch of biology, we are too open to the accusation of neglect of the important science of genetics, and if, as I hope, our profession is some day to lead the van, both educationally and politically, in the eugenic crusade, it is time we became more particular.—I am, etc.,

London, W.1, Oct. 28th. J. A. RYLE.

TUBERCULOSIS OF THE LARYNX.

SIR,—In his admirable paper on tuberculosis of the larynx in the recent issue of the *British Medical Journal* (p. 750) the distinguished writer expresses disappointment with the result of alcoholic injection of the superior laryngeal nerve for the relief of pain in this disease. I have used it many times and have almost invariably found it successful, and I have frequently been specially requested by my colleagues to carry it out in cases under their care. The effect is often quite dramatic, and many patients whose faces present a picture of misery, with distressing contortions on swallowing, are almost immediately after the injection able to swallow without pain and to show faces wreathed with smiles. The relief may last for days or weeks, and even permanently if the reaction of concomitant appropriate treatment is favourable.

The injection is indicated mainly in advanced cases when the ulceration in the larynx is too extensive for galvano-cauterization (see *British Medical Journal*, August 17th, p. 325). I think it is most effective when the ulceration is confined mainly to the aryteno-epiglottic folds, and least when the epiglottis is the chief site. The part taken by the superior laryngeal nerve in the innervation of the epiglottis is probably limited and is shared with the glosso-pharyngeal. Fortunately the epiglottis is accessible for other treatment.

I may state that I always inject in the thyro-hyoid space (*Lancet*, June 25th, 1910), where the nerve is so directly accessible that *it should be quite possible for the practitioner in charge to make the injection himself.* This is all the more desirable if facilities for the galvano-caustic treatment are not available.

Hoping that this suggestion may be helpful to those of your readers who have to deal with this very distressing class of case, I am, etc.,

London, Oct. 28th. JAMES DUNDAS-GRANT.

THE CONTROL OF MEASLES.

SIR,—I was much interested to read, in Dr. John D'Ewart's letter in your issue of October 19th (p. 737), the statement that "the mortality and morbidity of measles are the measure of the incidence of rickets." I have for some years held the same opinion from experience gained in Glasgow and Motherwell, and I do not recollect having seen it stated so precisely before. At various conferences in London and elsewhere, during the last three or four years, in discussing ultra-violet light work, I have stated that "most of the mortality from measles (and possibly whooping-cough) is, in my experience, associated with rickets, and I believe that the best way to prevent this mortality is not by the expensive method of hospital treatment of measles, but by the systematic eradication of rickets in infants."

This is a proposition of the highest importance to the public health, and its truth or otherwise should not be incapable of demonstration. I wish, however, now to supplement Dr. D'Ewart's remarks by suggesting that in any scheme for the prevention and cure of rickets exposure to light should be given a place not subsidiary to the provision of an adequate vitamin-containing diet. Throughout the summer, even in northern districts, much can be accomplished by teaching mothers to take every

available opportunity of exposing the skin of infants wholly or partially to sunlight, even for a few minutes per day. When these measures have failed and the first signs of rickets appear (how seldom are they looked for, how seldom diagnosed!) the ultra-violet light clinic, I believe, still holds the premier place as a therapeutic measure, not only for curing rickets, but for raising the standard of general health.—I am, etc.,

H. Stanley Banks;
Medical Superintendent.

Isolation Hospital and Sanatorium, Leicester, Oct. 22nd.

TREATMENT OF INFECTIONS WITH S.U.P. 36.

Sir,—With reference to my article on the treatment of influenza by S.U.P. 36 in the *Journal* of October 12th (p. 662), I have received several letters from epidemiologists interested pointing out that there is a serious omission in not giving the exact number of the control non-injected cases. It is also pointed out that the exact figures for each case, both of the non-injected as well as of the injected, should be given.

In the original typescript there was a table giving these figures in detail; this was omitted to save space. I myself suggested that it was not really necessary to print this. On consideration, however, it seems to be rather important, as its omission suggests that my controls might have been few and my records of their progress scanty. I would therefore ask you to be good enough to publish the table with this short explanation as an addendum to my paper.

May I take this opportunity of disclaiming any responsibility whatsoever for the offensive and misleading publicity which has been given to my paper in the lay press?—I am, etc.,

R. M. Pearce.

Halifax, Oct. 18th.

*** We appreciate Dr. Pearce's desire that the exact figures for each case—non-injected as well as injected—should be given, and gladly accede to his request for publication of his table. It is as follows (patients' initials have been omitted).

Patients Not Injected.							Patients Injected.

*This patient (case 27a) developed pneumonia.

P=Average duration of pyrexia in days. H=Average duration of headache in days. M.P.=Average duration of muscular pain in days. D.B.=Average number of days in bed. D.W.=Average number of days off work.

Sir,—The following observations upon the action of S.U.P. 36 and its allied compounds are put forward partly as a tribute to the genius of Mr. J. E. R. McDonagh, and partly to correct an impression gained from Dr. Thomson Brown's letter (October 26th, p. 785) that the utility of S.U.P. 36 begins and ends with catarrhal conditions. This is one of the hardest fields on which to assess its merits. I have been using these drugs since their commercial inception, and, like Dr. Douthwaite (October 19th, p. 739), I was disappointed with their effect in the first series of catarrhal conditions that I treated. The few rapid cures that occurred might have been explained by coincidence, particularly as I myself did not respond to injections for colds in any dramatic manner. I was subsequently induced to read the two volumes of *The Nature of Disease*, after which my interest in these remedies was renewed.

In order that the use of S.U.P. 36 may not suffer an untimely extinction its limitations must be realized. The whole conception of this group of drugs is founded upon a pathological theory which must be accepted, at any rate in part, as a working basis for their rational exposition. This theory is apparently so opposed to any classical teaching that we all must hesitate before admitting its truth. Ultimately one is convinced that the broad outlines are in accord with observed facts, and that the theory represents the nearest attempt yet made to reduce clinical medicine to an exact science. I give a brief list of diseases in whose treatment S.U.P. 36 has proved specific.

Hyperemesis Graviarum.—In severe vomiting of pregnancy 0.01 gram daily till vomiting ceases: I have never had to give more than three doses. This result is borne out by several of my colleagues, who have so far reported no failure.

Pyelitis.—A simple case—for example, resulting from a *B. coli* infection—will yield to two or three injections of 0.01 gram on alternate days. The administration may be followed by rigors, which are slight and in no way dangerous.

Broncho-pneumonia in Children.—A daily dose of 0.005 to 0.01 gram till the temperature drops: this seems an absolute specific.

Venous Thrombosis.—I give 0.01 gram every three days for three to five doses. The results are constant and sometimes dramatic; the usual time of resolution (six weeks) is at least halved.

Osteomyelitis.—If the infection is staphylococcal S.U.P. 36 will often resolve the condition without operation, and even if suppuration occurs it is far more superficial and localized than in an untreated case. In streptococcal cases S.U.P. 468 in 0.002 gram doses is necessary to effect an improvement.

Acute Cystitis.—These cases respond well to daily doses of 0.01 gram, and resolved in a few days.

Acute Mastoiditis.—I have treated with S.U.P. 36 every case of acute mastoiditis that has come under my care in five practices for two and a half years, and every one has resolved after two successive doses of 0.01 gram, leaving, in two cases, an otitis media, which soon cleared up of itself, and in the others septic tonsils, which were subsequently removed. As a routine these patients should be admitted to hospital or carefully watched, as it is too dangerous to regard the results of so small a series as evidence of a certain cure. So far, however, an immediate improvement has occurred from the first, and after the first twelve hours local surgical intervention has become quite unnecessary.

For the past two years every patient of mine submitted to major operation in the Victoria Hospital, Deal, has received 0.01 gram of S.U.P. 36 before operation, with a view to diminishing or preventing post-anaesthetic vomiting. That this result is achieved is difficult to prove, as most patients vomit at least once on returning to consciousness. A definite improvement in their general condition the day after operation is certainly evident. On no account should S.U.P. 36 be given during or immediately after anaesthesia, as there is grave risk of inducing pulmonary thrombosis; I have given it safely eight hours after operation. Post-operative pneumonia does not occur, even after partial gastrectomy; and post-operative sepsis and stitch abscesses are reduced almost to *nil*.

In conclusion, may I suggest to Dr. Thomson Brown that the specific for boils is manganese butyrate in 1 c.cm. doses of a 1 per cent. solution, and that a streptococcal infection of the throat will rapidly resolve with S.U.P. 468. So also will erysipelas and barber's rash, both of which are refractory to ordinary therapeutic measures.—I am, etc.,

James S. Hall.

Walmer, Oct. 26th.

ETIOLOGY OF RHEUMATISM.

Sir,—The second conclusion of Drs. Nabarro and MacDonald (*British Medical Journal*, October 26th, p. 759) states:

"This absence of difference fits in with the theory that there is no specific streptococcus which is the cause of rheumatism, but that the condition is due to a hypersensitiveness resulting from repeated small doses of toxin."

The term "toxin" could be elucidated further with some advantage, taking into consideration the recent work of Hitchcock, Lancefield, and others. Miss Lancefield[1] has isolated from the streptococcus three fractions: (1) a non-specific protein fraction; (2) a type-specific protein fraction; (3) a species specific carbohydrate. Of these, only No. 1 is a true antigen, and produces an antibody on injection; the other fractions do not produce antibodies when injected alone. Miss Lancefield has further shown that the nucleo-proteins of the non-haemolytic type are essentially alike in serological reactions,[2] and that there is a close relationship between the nucleo-proteins of the different strains. Hitchcock[3] has demonstrated that the nucleo-proteins of the haemolytic type are a homogeneous group. And Miss Lancefield has established that both haemolytic and non-haemolytic streptococci have a large fraction common to both nucleo-proteins.[4]

Is the toxin responsible for the hypersensitiveness the nucleo-protein which is common to the whole group of non-haemolytic streptococci? If so, an explanation is provided for the small importance of the type or variety of streptococcus involved. Rich[5] has shown that the allergic reaction is the property of the body cells rather than the fluids, and is an antigen-antibody reaction. This hypothesis would suggest that those symptoms of rheumatism due to hypersensitiveness are the resultant between the liberated nucleo-protein, common to all non-haemolytic streptococci, and the sensitized cells of the host.

This explanation, however, will not cover all the manifestations of rheumatism. Rich has suggested that the Aschoff body is analogous to the tubercle. Tubercle formation is claimed by Anderson[6] to be due to the lipoid fraction of Koch's bacillus. There is therefore a need for further research into the roles played by other constituents of the streptococcus in the causation of rheumatic disease.—I am, etc.,

Bristol, Oct. 28th. FRANK BODMAN.

TONSILLECTOMY AND RHEUMATISM.

Sir,—Drs. Nabarro and MacDonald, in their article on the bacteriology of the tonsils in relation to rheumatism in children, published in the *British Medical Journal* of October 26th (p. 758), quote many authorities who favour tonsillectomy as a prophylactic and therapeutic measure in rheumatic fever. They have entirely ignored the numerous investigators who have shown that tonsillectomy in this disease is of little, if any, value. With all deference, I would like to submit that the only fair summary of the evidence at present available is an admission that no adequate case has yet been made out either for or against this operation, and that "the undoubted advantages to be obtained from tonsillectomy in rheumatism" are only apparent after a biased consideration of the evidence.—I am, etc.,

London, W., Oct. 28th. A. ARNOLD OSMAN.

*** An article on tonsillectomy in the prevention and treatment of rheumatism, by Professor Leonard Findlay, Dr. James W. Macfarlane, and Dr. Mary M. Stevenson, of Glasgow, appears in the October issue of the *Archives of Disease in Childhood*, published by the British Medical Association.—Ed., *B.M.J.*

THE BURDEN OF DEAFNESS.

Sir,—The wearing of spectacles to aid the sight has been a common habit for so long that no one whose eyes are defective makes any fuss about it. But many people who are partially deaf are so self-conscious about the use of an instrument to aid their hearing that their disability becomes a burden to themselves and to their relations and friends. It is also a nuisance to everyone they have to speak to in daily life. The sufferer from deafness, if he refuses to avail himself of the help afforded by an instrument, hears, or partly hears, only a small amount of what is going on around him. Consequently his life is one of continual misunderstandings. In addition to this, he is always saying "What?" and straining forward to hear what is said. He does not hear unless people shout at him. He himself is liable to shout, because he cannot hear his own voice plainly, and so everyone within earshot hears what he has to say, whether it is a suitable subject for broadcasting or not. There is no privacy or decent reticence when such a deaf person is about.

The deaf, unaided by a suitable appliance, not only exhaust themselves with shouting and straining to hear, but may become an intolerable strain to their families, who have daily and hourly to repeat everything they say, and tire themselves out with their efforts. "There are none so deaf as those who won't hear" is a proverb which all deaf people may take to heart. A totally deaf person is a great rarity. There is hardly one who cannot hear quite well enough through an ordinary speaking tube. Aids for the deaf, whether they consist of ear trumpets, speaking tubes, or electrical instruments, are now so good that all can carry on a conversation in a normal tone of voice.

It is true that ear specialists can do much to prevent deafness, and to improve the hearing of those who have become deaf. In fact, many cases can be quite cured. But there is a very large residue of incurably deaf who could hear perfectly well if a false pride, or failure to appreciate the efficiency of the appliances devised to help them, did not stand in their way. It is only right that their friends and relations should know these facts in order to save themselves and the person afflicted with deafness an immense amount of unnecessary trouble. Great as is the disability inflicted by deafness—and I would be the last to minimize this—it is yet true that deaf people have some advantages which are denied to others; they need not hear if they would rather not, and in a world confronted with the problem of increasing noise this is a blessing. Furthermore, their very gesture of handing the mouthpiece of a speaking tube to an acquaintance is a request to him to say something worth hearing.

I should add that what I have written applies only to some deaf persons. There are, of course, others who behave habitually with the utmost consideration in order that their infirmity may cause the least possible inconvenience to others. I would not like to be thought—nor am I—lacking in sympathy for the deaf.—I am, etc.,

London, Oct. 22nd. H. MORTIMER WHARRY.

TWIN BREECH CONFINEMENT.

Sir,—The occurrence of a twin breech presentation is a matter of interest, but is it anything like as rare as suggested by Dr. F. G. Cawston (*British Medical Journal*, October 19th, p. 718)? According to Spiegelberg, in a series of 1,138 cases 8.6 per cent. both presented by the breech; the percentage according to Balfour Marshall is 9, and that given by T. W. Eden is 10.7. I take it that these percentages apply to all twin confinements. It is well known and quite obvious that malpresentation is more likely to occur in cases of twin labour than in labour with a single child. It is generally accepted, as stated by Dr. Cawston, that only one in sixty breech presentations comes to full term, but does this in any way affect the question of twin pregnancy? I think not, and according to the figures given I would expect one twin breech presentation

in every 900 to 1,000 births. If twins occur once in eighty confinements, as stated in Herman's *Difficult Labour* (Carlton Oldfield, 1920) and the percentage of double breech presentation is taken at ten, then the frequency would be increased to 1 in 800.—I am, etc.,

Huddersfield, Oct. 28th. S. H. WADDY.

LATE RESULTS OF ARTIFICIAL PNEUMOTHORAX.

SIR,—The value of collective methods of investigation has recently been emphasized by the success of the British Medical Association's inquiry into the treatment of varicose ulcers. Might I suggest that statistical evidence of great value might result from a similar inquiry into the late results of artificial pneumothorax therapy?

That this method of treatment is of real value is suggested by the fact that all those who have practised it on any considerable number of patients are unanimous in its praise; this was well shown by Burrell and McNalty (Report of Medical Research Council, No. 67). In order to convince the sceptic, however, statistical evidence is necessary. Artificial pneumothorax is no new form of treatment, and such evidence should be obtainable now. The published results of certain foreign investigators, such as Saugman and the Matsons and Bisailloa, are valuable and suggestive, but to bring conviction they need the confirmation of a carefully controlled inquiry on a large scale. I suggest that a questionary sent to various institutions and individuals in this country might yield very valuable data. For instance, the survival rate of patients four years after commencement of artificial pneumothorax treatment might be compared with the survival rate of putum-positive patients who have been subjected to other methods of treatment. If artificial pneumothorax is of real value then many lives are being needlessly lost.—I am, etc.,

Burley, Hants, Oct. 26th. R. L. OSMASTON, M.R.C.S., L.R.C.P.

Obituary.

WILLIAM BEVAN-LEWIS, M.Sc., M.R.C.S.,

Late Professor of Mental Diseases and Examiner in the University of Leeds.

WE regret to record the death of Dr. W. Bevan-Lewis on October 14th, at the age of 82.

William Bevan-Lewis was born at Cardigan, and received his medical education at Guy's Hospital; he obtained the diplomas M.R.C.S., L.R.C.P., and L.S.A. in 1868. After four years spent in private practice at Burry Port he joined the staff of the West Riding Asylum at Wakefield, becoming successively pathologist, senior assistant, medical officer, and, lastly, medical superintendent and director. While he was at Wakefield he inaugurated the new hospital for acute mental diseases, the new home for the imbecile and feeble-minded, and an out-patients' department. He was also responsible for a complete re-modelling of the pathological department. After thirty-five years' work at the Asylum he joined the staff of the University of Leeds, where he was lecturer, examiner, and, subsequently, professor of mental diseases. Dr. Bevan-Lewis was a member of the British Medical Association, and was president of the Section of Psychological Medicine at the Annual Meeting at Nottingham in 1892. He was also vice-president of the Physiological Section when the British Association met at York in 1906. He was the author of a number of text-books and publications on mental disease, including a *Students' Manual of Examination of the Human Brain*, a *Text-Book of Mental Diseases*, and the section devoted to the general pathology of the nervous system in Allbutt's *System of Medicine*.

We are indebted to Sir JAMES CRICHTON-BROWNE for the following appreciation.

With Dr. William Bevan-Lewis has passed away one of the most diligent and productive of labourers in the field of medical psychology in this country during the last quarter of the last century and the first decade of that through which we are hurrying along. With few outside interests, he was wedded to medical psychology, regarded it with an affection only second to that which he bestowed on his over-helpful wife, and notably contributed to its advancement, on both its practical and scientific sides.

After completing his studies at Guy's Hospital, and qualifying, Bevan-Lewis, then 21 years old, became assistant medical officer at the Buckingham County Asylum, but after being there for two years, and having married, yielding to the wish of his family, he commenced private practice in Cardigan, his native town. But he had been strongly attracted to the study of mental disease, and the call of the laboratory was upon him. He soon found that his occupation in a mountainous district of Wales was uncongenial, and left him no opportunity for the research work in which he earnestly desired to engage. He sought, therefore, to re-enter the lunatic asylum service, but at that time there was not an asylum in England that provided accommodation for a married assistant medical officer, and so, after several attempts, he failed to get his foot on that ladder again. He ultimately, as a forlorn hope, applied to me, I was on the look-out for talent, and happily discerned his zeal and ability. I succeeded in making the necessary arrangements, so that he and his wife took up their abode at the West Riding Asylum in the beginning of 1875. He came there as a clinical assistant without pay, though board and lodging were provided, but promotion was rapid at the West Riding Asylum in those days, and within a few months he was appointed medical assistant and pathologist. In that capacity he continued to act under my medical directorship until I became a Chancery Visitor in April, 1876. My official relations with him were of the happiest description, and ripened into warm friendship, which subsisted unchilled until his death.

During the eight years after I left Wakefield I was in constant communication with Bevan-Lewis, and knew what excellent work he was doing in the research laboratory and as deputy medical director, which he had become; but I confess that when he was appointed to the chief charge in succession to Dr. Herbert Major, in 1884, I had doubts whether, with all his ability, the somewhat delicate, studious, and retiring subaltern, with keen Cymric sensibility, would be equal to the administrative control of a great mental hospital with 1,600 beds, gradually expanding, and with a certain reputation to maintain. His predecessor had found the burden too oppressive. But "as thy days, so shall thy strength be," and my doubts were speedily dissipated. From the first Bevan-Lewis, by his rectitude, assiduity, and modest self-possession, secured the confidence of his staff and his committee, and for twenty-six years he remained the trusted and esteemed head of the institution and the beloved physician at the bedside.

Not only did Bevan-Lewis maintain unsullied the best traditions of the West Riding Asylum, but he extended its usefulness and introduced some new developments. He created a dispensary or out-patient department, the first experiment of the kind attempted in an asylum in this country; he made special provision for the education and training of the weak-minded; he established a reception block, furnished with all the most modern apparatus for clinical observation and research; and he constituted the asylum in some measure a post-graduate school, for he opened it for short periods of residence to young medical men anxious to obtain some special knowledge of mental and nervous disease. Many who availed themselves of the privilege thus offered, and who have since attained professional distinction, together with many of the students who attended his class at the Leeds School of Medicine, afterwards the University of Leeds, will bear testimony to the stimulating nature of his teaching, and to the charm and encouragement of his personal influence.

Of Bevan-Lewis's manifold scientific labours and achievements it is impossible to give here anything but the barest outline. His first contribution to medico-psychological literature was a paper published in the *West Riding Asylum Medical Reports* for 1875, on "The histology of the sciatic nerve in general paralysis"; in this he described degenerative changes in peripheral nerves in the advanced stages of that disease, and correlated these with the spinal changes in locomotor ataxia. This was followed in the *Reports* of 1876 by a careful calorimetric study of "The influence of

various alkaloids on the generation of animal heat." In the *Proceedings of the Royal Society* for 1878 there appeared a paper on "The lamination of the motor area of the brain," and in *Brain* of the same year there was a paper on "The comparative structure of the cerebral cortex," which was the starting-point of those discoveries in histological localization of the cerebral cortex by which he will be best remembered. While on the editorial staff of *Brain* I received from Bevan-Lewis invaluable assistance, and it was in its pages that appeared the series of articles on "The methods of preparing, demonstrating, and examining cerebral structure in health and disease," which were afterwards collected in book form with the title of *The Human Brain: Histological and Coarse Methods of Research*, and published in 1882.

It was in 1889 that Bevan-Lewis issued his *magnum opus*—his *Text-Book of Mental Diseases*—the product of years of elaborate investigation, a book now forty years old, but that still in many respects holds its own, and has not been altogether squeezed out by the multitude of textbooks that have since emerged, especially in the United States. The *Text-Book* is much more than a textbook, being really a compendious system of psychological medicine. It embodies all the author's histological observations, with admirable illustrations; it supplies life-like studies of the symptoms of the various forms of mental disease, studies that could not be bettered to-day. There have, of course, been great advances in etiology and treatment since the *Text-Book* was written, but in its clinical and pathological sections it is still abreast of our knowledge of to-day. Enormous pains were expended on its preparation, and it is singularly lucid in style. In later years Bevan-Lewis continued to contribute to *Brain* and the *Journal of Mental Science* thoughtful essays on alcoholism, crime, and insanity; on the neuron theory; and on rest and sleep.

Bevan-Lewis received the honorary M.Sc. degree of the University of Leeds in 1905, and was president of the Medico-Psychological Association in the same year. The value of his work has been fully appreciated by his own specialty at home and abroad, and has been widely recognized by the profession at large. That it did not receive the higher acknowledgement it deserved was no fault of mine or of Sir David Ferrier. One of the gentlest and most unobtrusive of men in an age when notoriety is the universal quest, Bevan-Lewis persistently kept himself in the background.

ROBERT JAMES SMITH, O.B.E., M.B., B.Ch.,

Coroner to the City of Cardiff, and Past-Chairman of the Cardiff Division.

THE sudden death, on October 23rd, of Dr. R. J. Smith, which occurred in a nursing home at Chichester while he was on holiday, removes from the public life of Cardiff not only a distinguished medical practitioner, but also one of her leading citizens.

Robert James Smith, born fifty-seven years ago in Middleton, County Cork, the son of the late Rev. John A. Smith, chaplain to H.M. Prisons, received his medical education at Queen's College, Cork, and University College, Cardiff. In 1896 he graduated M.B., B.Ch., B.A.O. of the Royal University of Ireland, and obtained the D.P.H. of the Royal Colleges of Physicians and Surgeons of Ireland in 1911. In 1897 he went to Cardiff to take up an assistantship. Despite the obligations incurred by a busy general practice, he always took a keen interest in municipal affairs, and in 1903 he was elected to the city council to represent the Grangetown Ward in the Conservative interest. He held this seat for eighteen years, and weathered many contests until his resignation in 1924, on his appointment to the office of city coroner. During this period he acted on many municipal committees, of some of which he was chairman; he was elected alderman in 1909, and in 1915 was elected Lord Mayor of Cardiff, being one of the youngest and most popular men who have held this office. His public interests were many, and he gave of his time unstintingly to them. He was chairman of the Grangetown Old Age Pensions Committee, and of the Cardiff and County Public Health Laboratory Joint Committee; he was also lecturer to the St. John Ambulance Association and to the Red Cross Society. His professional interests were equally wide. He was a member of the board of management of Cardiff Royal Infirmary, a member of council of University College of South Wales and Monmouthshire, and physician to the Welsh Metropolitan War Hospital; he held a commission in the R.A.M.C. during the latter part of the war, and was awarded the O.B.E. for his services. He was also an active member of the British Medical Association, and during the Insurance Act disputes became very prominent; in 1913-14 he was chairman of the Cardiff Division of the Association.

A colleague writes: It was in his personality that Dr. Robert Smith excelled. With the fluent tongue of his country he was a ready speaker and debater; he was always prepared to give and take the hardest knocks, but he took them in the best of spirits, and expected them to be accepted by others in the same way. He never harboured malice or ill feeling, and any underhand action or unjust thought regarding a man was impossible in him. In his duties as coroner he was most kindly and tactful, and always anxious to save the feelings of relatives of the deceased. He held his duties and his profession in the highest regard. Formerly a most active man, he contracted a slight hemiplegia a few years ago, and, although he made a most satisfactory recovery, he was never since then the same old "R. J." that we knew. The spring was loosened, and he quite suddenly became an elderly man. The death of a brother and a sister during the present year was a great blow to him, and saddened his latter days. He was a bachelor, and lived with his devoted twin sister, Miss M. A. Smith, to whom widespread sympathy is extended at this time. The funeral, on Saturday, October 26th, was one of the largest ever seen in Cardiff. Besides relatives and a very large number of his professional colleagues and friends in Cardiff and district, the city police and the St. John Ambulance were represented, while the Lord Mayor and City Corporation were present at the graveside. The Cardiff Division of the Association was represented by Dr. Robert Walker, its chairman, and Drs. Williamson and Pearson, the honorary secretaries.

DR. HERBERT WILLIAM CHAMBERS, who died on September 20th at Worthing, was born in 1862 at Lowestoft, and received his medical education at St. Bartholomew's Hospital. He obtained the diplomas M.R.C.S., L.R.C.P. in 1884. After holding the appointment of house-surgeon at Hull Royal Infirmary, he engaged in general practice in Yorkshire for five years. In 1892 he came to London, where he practised for thirty-five years, until his retirement in 1927, when he went to Worthing. He became a member of the British Medical Association soon after qualifying, and was subsequently elected vice-president of the Metropolitan Counties Branch and chairman of the Kensington Division. Throughout his professional career he was devoted to the West London Medico-Chirurgical Society, which he joined in 1892. He soon became a personal friend of many on the staff of the West London Hospital, among whom, in the early days, was Charles Bell Keetley, F.R.C.S., the founder of the society. Dr. Chambers's close friendship and association with Keetley did much to inspire his lifelong interest in this society. He was editor of the society's journal for many years, secretary, and, finally, president in 1919, afterwards remaining on the council until recently. His presidential address was entitled "The history of London medical societies." Dr. Chambers also took a deep interest in the Invalid Children's Aid Association, and was chairman of the Hammersmith branch. He was an ardent and zealous Freemason, and held many high and important offices in the craft, where his death has been deeply deplored. He was an enthusiastic philatelist, and his collection of stamps was well known among London collectors. Throughout his life he always aimed at the highest ideals of professional conduct and practice. His personality and wide experience of his profession earned for him the lasting gratitude, respect, and esteem of patients, colleagues, and friends, to whom his loss has been a deep and personal one. Dr. J. F. Halls-Dally writes: For many years I had the great privilege of being brought into close association with

the late Herbert Chambers, and of enjoying his genial friendship. By reason of many excellencies of character he was beloved by his friends, whilst by a still larger circle of acquaintances he was also held in the highest esteem. The West London Medico-Chirurgical Society, in particular, owes his memory a deep debt of gratitude for long personal service to the society, extending over a period of thirty-seven years. During this time he gave of his best to further its aims and objects, holding as he did no fewer than six of its executive offices, including that of the presidency, to which, in 1919, he was elected after ten years' most able editorship of its journal. In Masonic circles he was a familiar and distinguished figure. Master of the Cavendish Lodge in 1914, he had been its valued treasurer since 1920. In the Freemasons Hospital he took a deep and abiding interest. His professional attainments were such as caused him to be respected alike by his patients and colleagues, and in private and public life his death is widely and severely felt.

THE LATE DR. J. DAVENPORT WINDLE.

A FORMER colleague (A. J. W.) writes:

In the death of Dr. Davenport Windle medical science and medical practice have suffered a grievous loss. My association with him dates from the pre-war days when we were both workers together in the heart wards of the old Mount Vernon Hospital at Hampstead. We were then in valued association with James Mackenzie, A. R. Cushny, and many others keenly interested in that branch of medicine. Among the keen he was one of the keenest, and as a practical exponent of the graphic method there was none superior if any equal. Windle made valuable original contributions at that time to what has become known as cardiology, particularly perhaps in respect of sinus arrhythmia in children, pulsus alternans in the aged, with special reference to prognosis, and Cheyne-Stokes breathing as met with in cases of heart disease. Devoted to the interests of the individual patient in his onerous practice, he was a source of inspiration and helpfulness to his fellow workers in hospital. Able, kindly, considerate, and unselfish, he was truly a fine example of the present-day medical practitioner.

The Services.

STANDARDIZATION OF FIELD MEDICAL EQUIPMENT.

CONGRESS OF THE PERMANENT INTERNATIONAL COMMISSION.

THE fourth meeting of the permanent international commission on the standardization of field medical equipment was held in Geneva from October 7th to the 14th. It was convened by the International Red Cross Council, and was attended by representatives of Belgium, France, Germany, Great Britain, Holland, Italy, Poland, Rumania, Spain, Sweden, and Switzerland. The permanent committee of the Congress of Medicine and Military Pharmacy was represented by its general secretary, Major J. Voncken. Inspector-General Marotte of France, who had presided over the third meeting of the international commission, was re-elected to that office, and Lieut.-Colonel van Baumberghen of Spain was elected vice-president. In a preliminary meeting it was agreed to establish liaison between the permanent committee of the International Congress of Medicine and Military Pharmacy, through the agency of the general secretary of the last-named.

Standardization of Stretchers.

As regards the adaptation of the field stretcher for conveyance by vehicles on wheels, it was agreed, in the first place, that such vehicles were undoubtedly valuable auxiliaries to the hand carriage of the wounded, especially over flat surfaces. Although it was not at present possible to adopt a standard pattern, the following characteristics were defined as being essential. Stretchers should be transportable by the ordinary or special means of conveyance, and, therefore, they should be constructed to be as *light* as possible, while being strong enough to resist all rough handling. They should be no more cumbersome than was inevitable, and any interchangeable parts should be easily detachable. Simplicity must be the keynote both as regards their construction and their carrying and setting down. The parts of which they were composed should be durable, easily and cheaply replaceable, and convenient for storing. Stretchers should be as little visible as possible when on the ground; be comfortable for wounded patients, even during motion; and be quite stable, whether moving or at rest. It ought to be possible to change at will from wheeled to manual transport, and *vice versa*, with the aid of a minimal staff. The commission issued an urgent request to the military medical authorities of the nations interested to send as soon as possible, and in any case not later than March 1st, 1930, to the medical headquarters of the Belgian army in Brussels the models in use, or being tested in their respective armies, together with details about the manner of their employment and their construction.

Adaptation of Stretchers for Transport by Air.

From a preliminary investigation which had been made of the problem of adapting field stretchers for transport by aeroplanes the commission drew the following conclusions. To prevent or minimize disturbance of the sick and wounded the aeroplanes intended for their conveyance ought to be constructed so as to receive the standardized field stretcher. Since it was obvious that the transport of the sick and wounded could not be always effected by such specially constructed aeroplanes, it was held to be desirable that military, as well as civil, aeroplanes should be adapted to carry the standardized stretcher, a matter which did not seem to raise any *a priori* difficulty. The following subjects were selected for further investigation: (1) the essential principles concerned in adapting these standardized stretchers for aerial transport; (2) the provision of absorbers to minimize shock during shoulder carrying and setting down; (3) methods of rendering ordinary aeroplanes suitable for the transport of the sick and wounded. The commission invites military medical authorities to send as soon as possible, and in any case before March 1st, 1930, to the Central Association of the Italian Red Cross in Rome, any publications, models, designs, plans, and photographs, with a view to making the catalogue fully comprehensive.

Conversion of Stretchers into Operating Tables and Beds.

The commission approved the following principles: (1) The height of the operating table appliance when in use should be 5 to 10 cm. more than that of an ordinary table. The height of the bed appliance should be 50 cm. from the ground. (2) All such appliances should be characterized by such solidarity and stability as would meet vertical, longitudinal, lateral, and diagonal strains without causing sliding over their supporting bases; the area of these bases should not exceed 10 cm. (3) The appliances might be constructed according to one or other of three designs to secure stability: provision of two supports in a special frame; or of two supports furnished by the stretcher itself; or of two separate supports. (4) Other conditions being equal, the first two of these supporting methods had been shown to be preferable to the third. (5) The first two of these designs should permit the reception at each end of a weight of 160 kilograms; in the third case each support should be able to bear this weight independently. (6) These appliances, in view of their transportability, should be of as small a bulk as possible; they must be light, involve the minimum of separable parts, and be capable of being rapidly loaded. (7) It might be worth while for these operation tables and beds to incorporate movable supporting surfaces, easily attachable to the underside of the stretcher; such surfaces would have to be as light as possible, and have no projecting portions.

The commission invites the attention of manufacturers to the following points. For fixing the supporting surfaces it is necessary to remember the differences in height and breadth of the handles, which vary according to the type of stretcher, from 2½ to 7 cm.; another point to be borne in mind is the narrowing involved by the displacement of these handles due to the weight of the patient or the nature of the canvas. It is recalled that the handles of stretchers must allow a free space of 119 cm. for their suspension or support from below, and that the supporting surface must allow on each side a margin of at least 10 cm.

Vehicles for Transport of the Sick and Wounded.

A preliminary survey of the problem of vehicular transport has made it clear that it will be best to investigate separately the applicability of horse-drawn vehicles with two or four wheels, and automobiles. In order to make a start the commission has placed on the agenda for the next session of the international commission the general characteristics which these vehicles must have. They must provide the maximum degree of comfort in bad weather and in compensating for jolting. The best forms of heating, lighting, and ventilation must be adopted. They must afford protection against gas attacks, and facilitate rapid cleansing and disinfection. They must be readily adaptable for the carriage of the standardized stretchers and the previously mentioned accessories. Loading and discharging should be easily and rapidly accomplished.

The commission urgently requests the military medical departments of the nations which are co-operating to send as soon as possible (and not later than March 1st, 1930) to the medical

headquarters of the Rumanian Army in Bucarest all documents, sketches, plans, photographs, and other information relating to such vehicles for transporting the wounded which have been, or are being, used in their armies. Details are particularly desired as regards their weight, dimensions (including length and inside width), lighting, facility for carrying stretchers, and their capability of being produced in wartime.

Medico-Legal.

A SURGEON'S FEE.

IN its issue of October 18th the *Surrey Mirror and County Post* reports a further stage in the legal proceedings by Dr. M. W. Baker and his partner, Dr. C. H. Laver, of Redhill, to which reference was made in this column on October 19th (p. 741). The amount of the fee claimed (£21), with costs, had been paid into court by the Reigate Corporation, but there was an application by the plaintiffs for costs on a higher scale.

The case was heard in the Redhill County Court on October 16th, before Judge Hill Kelly. Mr. Denning, barrister-at-law, on behalf of the plaintiffs, explained that the operation had been performed by Dr. Laver on one of the child patients at the isolation hospital for an acute mastoid. The charge of 20 guineas had been subsequently disputed by the corporation, which alleged that this was unreasonable and excessive, and offered five guineas. This Dr. Laver and his partner considered insufficient for a major operation of that nature, but when they protested the corporation suggested that an action might lay against Dr. Fardon, medical officer to the hospital. The plaintiffs were not disposed to adopt this course, hence the present action, which might be regarded, perhaps, as in the nature of a test case as to whether a public body running a hospital was responsible in such circumstances as those described. There was a novel and important point of law involved as to the liability of the corporation, and one which was of considerable interest to the medical profession generally.

Judgement was entered for the plaintiffs, whose application in respect of the costs was likewise upheld, Judge Hill Kelly holding that these had been reasonably incurred.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Reassembly of Parliament.

PARLIAMENT reassembled on Tuesday, October 29th, when the Collecting Charities (Regulation) Bill was discussed and its second reading deferred. The Widows Pensions Bill was down for second reading on October 31st.

On October 29th Mr. SNOWDEN, in announcing the Government's programme of business, said that it was proposed to proceed with the Unemployment Insurance Bill before the Christmas adjournment, and to make progress with other measures foreshadowed in the King's Speech, including the Factories Bill, to regulate hours of industrial employment. The financial resolution for the Highlands and Islands medical services would be placed on the Order Paper next day, and a White Paper on the subject would be available. It was understood in the Lobby that the Highlands and Islands (Additional Grants) Bill would be introduced during the week.

In the ballot for notices of motion, on October 29th, Dr. FREMANTLE gave notice that next week he would call attention to "ribbon development," and move a resolution. Mr. T. HENDERSON gave notice of a motion on the nationalization of water supply.

On October 29th Dr. FREMANTLE asked Mr. Snowden whether the promised measure for slum clearance was included in the bills to be introduced, or if it was not considered of sufficient importance to be introduced before Christmas. Mr. SNOWDEN said he hoped that when the bill was introduced it would be recognized that it was a bill of first-rate importance. It would be taken as soon as parliamentary time permitted.

Motor Accident Cases in Hospitals.

Mr. CLYNES, in reply to a question by Mr. Louis Smith, on October 29th, said that he had consulted the Minister of Health, and was advised that the number of accidents treated in local hospitals and resulting from the use of motors, from April to October, could not be ascertained without imposing great labour on the police, out of all proportion to the usefulness of any results. He did not see his way to ask the police to furnish the information.

On the same day Sir W. DAVISON asked the Minister of Transport whether, in view of the serious cost and difficulties thrown on voluntary hospitals in the receiving and treating of persons suffering from motor accidents, and also in view of the fact that in very many cases no payment is made to the hospital in question by such persons for their treatment in the hospital, the Government would consider the propriety of raising a central fund by means of a small deduction from driving licences, or otherwise, with a view to adequate payments being made to voluntary hospitals, which are unable to obtain payment for services rendered in the case of motor accidents. Mr. H. MORRISON said that he did not feel justified in recommending the legislation which would be required to impose a compulsory levy on the drivers of all motor vehicles for this purpose.

Sir W. DAVISON asked if the Minister of Transport did not recognize that many hospitals kept a special ward for dealing with motorists' accidents, which interfered with the normal work of the hospitals, and was a great expense to them when they already found it difficult to pay their way. He asked if the Minister could not introduce some clause in the legislation which he had promised with regard to third-party insurance which would deal with this matter. Mr. MORRISON replied that they all recognized the financial difficulties of voluntary hospitals, but he was unable to agree that this was exclusively related to the services required from the hospitals by motorists.

Mr. ALBERY asked the Minister to approach the Automobile Association and the Royal Automobile Club with the suggestion that they should try to devise means of collecting sums for the hospitals. Mr. MORRISON replied that there was no reason to believe that motorists as a class were less generous in their contributions to hospitals than any other section of the community. It would be difficult to single them out from other users of the hospitals.

Coroners' Inquests.—On October 29th Sir KINGSLEY WOOD asked the Home Secretary whether he was aware of the considerable public apprehension concerning the recent conduct and procedure of certain coroners' inquests in relation to the ancient and well-established rights and liberties of the subject, and whether he could make any proposals in the matter. Mr. CLYNES said that the law relating to coroners' inquests was revised and brought up to date by a comprehensive measure only three years ago. The view, in which the Lord Chancellor and the Attorney-General concurred, was that it would be a mistake so soon after the revision of the law to consider making another fundamental alteration because of what had happened in one or two quite exceptional cases. He proposed, therefore, as at present advised, to take no action in the matter.

War Pensions.—On October 29th Mr. F. O. ROBERTS, replying to a question, said that he expected to be able shortly to make a full statement on the Government's attitude regarding the abolition of the seven years' limit in regard to ex-service men. He was giving close attention to all difficulties in administration of war pensions, and would do what was possible from time to time to remedy them.

Administration of Factory Acts.—On October 29th Mr. SNOWDEN told Mr. Graham White that the question of the transference of the administration of the Factory Acts to the Ministry of Labour was under the consideration of the Government.

Universities and Colleges.

UNIVERSITY OF LONDON.

Meeting of the Senate.

A MEETING of the Senate was held on October 23rd, when the Vice-Chancellor (Sir Gregory Foster) was in the chair.

The degree of D.Sc. in Medical and Vital Statistics was conferred upon Mr. A. B. Hill, an internal student of the London School of Hygiene and Tropical Medicine, for a thesis entitled "An investigation of sickness in various industrial occupations."

Sir Cooper Perry was appointed a governor of Holloway Royal College, and Professor H. R. Kenwood, Sir William Simpson, and Sir Holburt Waring governors of the London School of Hygiene and Tropical Medicine.

UNIVERSITY OF EDINBURGH.

A GRADUATION ceremonial was held in the Upper Library Hall on October 26th.

The degree of D.Ph. in the Faculty of Medicine was conferred on J. R. Greig, M.R.C.V.S., for his thesis on acute calcium deficiency in farm animals, with special reference to milk fevers in cows.

The Diploma of Public Health was conferred upon H. J. Gibson, D. Lennox, K. A. T. Martin, S. Narain, and N. S. Turnbull.

UNIVERSITY OF GLASGOW.

Appointment of Principal.

THE KING has approved the appointment of Professor Robert Sangster Rait, C.B.E., LL[illegible] Scotland, to be Principal of the [illegible] on to Sir Donald MacAlister, [illegible] held the Chair of Scottish History and Literature in the University since 1913.

NATIONAL UNIVERSITY OF IRELAND.

THE following awards have been made: Pierce Malone Scholarship in Mental and Moral Science, M. P. O'Connell; Dr. Henry Hutchinson Stewart Medical Student Scholarships—anatomy, D. K. O'Donovan and J. J. Linehan (scholarship divided); physiology, J. K. Feeney.

Dr. J. McGrath has been appointed lecturer in medical jurisprudence at University College, Dublin.

The Dr. Henry Hutchinson Stewart Scholarships in arts, medicine, and mental and nervous diseases will be offered for competition in 1930.

Medical News.

The forty-sixth annual dinner of the past and present students of the School of Medicine, Leeds, will be held on Friday, November 8th, at the Hotel Metropole, Leeds, under the presidency of Mr. S. W. Daw, F.R.C.S.

The annual dinner of the London (Royal Free Hospital) School of Medicine for Women will be held at the Savoy Hotel (Embankment entrance) on Thursday, December 5th, at 7 for 7.30 p.m., under the chairmanship of Mr. Joseph Cunning, senior surgeon to the hospital.

The annual dinner of the staff and past and present students of the Royal Dental Hospital of London will be held, at 7 p.m., on Saturday, November 23rd, at the Trocadero Restaurant, with Mr. W. J. May in the chair. The Medical Committee will be "At Home" to all past and present students of the hospital on the same day, from 9.30 a.m. to 5 p.m. In the morning demonstrations will be given, and in the afternoon orthodontic and other cases of special interest will be shown. The various departments of the hospital and school will be open for inspection.

The annual dinner of the Prince of Wales's Hospital Reunion Association will be held at the Holborn Restaurant on Thursday, November 21st, at 7.45 for 8 p.m., with Mr. T. H. C. Bevians in the chair. Price of dinner (exclusive of wines) 12s. 6d.; no tickets will be issued. Members are asked to notify the hon. secretary, Dr. Bruce Williamson, 137, Harley Street, W.1, of their intention to be present, stating number of guests.

The next quarterly meeting of the Royal Medico-Psychological Association will be held at the British Medical Association House, Tavistock Square, W.C.1, on Wednesday, November 6th, at 2.30 p.m. Papers will be read by Dr. T. Saxty Good on some experiments with suggestion and association tests in the feeble-minded, and by Dr. Geoffrey Shera on *Bacillus acidophilus* deficiency in mental patients, with notes on the ancillary flora.

At a meeting of the Pharmaceutical Society of Great Britain to be held at 17, Bloomsbury Square, W.C., on Tuesday, November 12th, at 8.30 p.m., a lecture will be given by Dr. E. N. da Costa Andrade, Quain professor of physics, University of London, on modern views of matter. Medical friends of members and student-associates will be welcomed.

The first of a series of lectures on racial and individual welfare, arranged by the People's League of Health, will be delivered to-day (Friday, November 1st) at the Medical Society of London, Chandos Street, Cavendish Square, W.1, at 6 p.m., by Dr. A. F. Tredgold, on the subject of inborn qualities in regard to national health.

A conference on the international control of opium and dangerous drugs will be held at the London School of Economics on Wednesday, November 13th, under the auspices of the Women's International League, and in response to an appeal from the Chinese Anti-Opium Society. The Women's International League is organizing a series of conferences in different European countries, through its national sections, in order to obtain instruction from experts, and to educate public opinion. At the conference on November 13th there will be speakers from India, China, and Egypt, including Mr. P. J. Noel Baker, M.P., and Mr. Lyall, chairman of the Permanent Central Opium Board of the League of Nations. The sessions and subjects of the conference will be as follows: *10.30 to 1 o'clock*, Present Position; 2.30 to 4.30, Possible Remedies; 5 to 6.30, Discussion. Admission is free to all sessions, and seats will be reserved on request to the secretary, Women's International League, 55, Gower Street, W.C.1.

The annual congress of the British Institute of Radiology, incorporated with the Röntgen Society, will be held at the Central Hall, Westminster, on December 4th, 5th, and 6th, during which time there will be a trade exhibition of *x*-ray apparatus. The Sylvanus Thompson and Mackenzie Davidson Memorial Lectures will be given in the congress hall adjoining the exhibition.

The Royal Sanitary Institute will hold a sessional meeting on Friday, November 15th, at 7.30 p.m., in the Town Hall, Carlisle, when discussions will take place on town planning of built-up areas, the dangers and difficulties of small water supplies, and the veterinarian in relation to the milk supply.

A course of post-graduate lectures at King's College Hospital Medical School commenced on October 10th, and will be continued on successive Thursdays till March 27th, 1930, with the exception of December 19th and 26th, 1929, and January 2nd and 9th, 1930. The lectures, which will be given in the lecture theatre of the Medical School at 9 p.m., are free to medical practitioners and to final-year students of King's College Hospital. Coffee will be served at 8.45 p.m.

A new course of post-graduate lectures at the Royal Northern Hospital, Holloway Road, N.7, will commence on Tuesday, November 5th, at 3.15 p.m., and continue weekly until March 30th next. During an intensive week, December 2nd to 6th, lectures and demonstrations will be held daily at 2.15 and 3.15 p.m. The full programme of the course, which is open free to all medical practitioners, may be obtained from the dean of the hospital.

The Fellowship of Medicine announces that the following lectures will be given in the lecture-room of the Medical Society of London, 11, Chandos Street, Cavendish Square: on Monday, November 4th, at 5 p.m., Mr. W. B. Gabriel will speak on common rectal complaints (no fee); on Tuesday evening, November 5th, at 8.30, Dr. J. W. McNee will discuss the structure and functions of the spleen in relation to its diseases; and on Friday evening, November 8th, at 8.30, Dr. O. L. N. de Wesselow will speak on nephritis and oedema. The last two lectures are especially suitable for M.R.C.P. candidates. A demonstration on gastric diagnosis will be given at the Royal Waterloo Hospital by Dr. Cecil Bull on November 6th, at 10 a.m., and there will be a demonstration of throat operations by Mr. W. Ibbotson on November 6th, at 2 p.m., at the Prince of Wales's Hospital, Tottenham; both demonstrations are free to medical practitioners. Three special courses start on November 4th; the first, at the Royal Waterloo Hospital, in medicine, surgery, and gynaecology, will continue for three weeks, occupying each afternoon and some mornings; the second, at the London Lock Hospital, will be held each afternoon and most evenings for four weeks, dealing with venereal disease; the third, an afternoon course in ophthalmology at the Central London Ophthalmic Hospital, will last for four weeks. Other courses in November deal with orthopaedics (November 18th to 30th), proctology (November 25th to 30th), and neurology (November 18th to December 13th). Detailed syllabuses of all courses and the advance list of special courses for 1930 may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

A post-graduate course will be held in Vienna, from November 25th to December 8th, dealing with the internal secretions and their relation to the general constitution. Details of this and of other shorter courses to be held can be obtained from the secretary of these international courses, Dr. A. Kronfeld, Porzellangasse 22, Vienna IX.

A medical tour to the Riviera will be conducted from December 26th to January 8th, and include excursions into Italy, the Alps, and Corsica. The places to be visited include Marseilles, Aix-en-Provence, Toulon, Hyères, St. Raphael, Le Cannet, Grasse, St. Juan-les-Pins, Nice, Mentone, Bordighera, St. Remo, Monaco, and Beaulieu. Further information regarding the tour may be obtained from the manager of the Federation of the Health Resorts of France, 1, Gordon Square, W.C.1.

The October issue of *Leprosy Notes*, the quarterly publication of the British Empire Leprosy Relief Association, contains an article by the editor, Dr. R. G. Cochrane, on the position of iodides in the treatment of leprosy. Dr. Cochrane maintains that iodides should only be given to the healthy leper, those who have flabby muscles or who are physically weak being unsuitable for this treatment. Administration should be stopped as soon as the treatment begins to produce weakness. Dr. J. L. Maxwell discusses the problem of leprosy in China, with special reference to migration; while the treatment of this condition in Weihaiwei is considered by Dr. F. Clark, who reports on the use of alepol, or sodium hydnocarpate, in treatment. Sir Leonard Rogers contributes a short note on the therapeutic and economic value of work for lepers. The leprosy problem in Canada is discussed by Dr. J. D. Page of Ottawa, who urges that more attention should be paid to this disease by practitioners and those responsible for medical education.

Dr. Rouvillois, director of the Val-de-Grâce School of Military Medicine, and Dr. Le Noir, formerly physician to the Hôpital St. Antoine, Paris, have been elected members of the Académie de Médecine.

Professor Luis Morquio of Montevideo has been created a chevalier and Dr. Gustave Humbert of Geneva an officer of the Legion of Honour.

The following appointments have recently been made in foreign faculties of medicine: Frau Privat-docent Golant-Ratner has succeeded the late Professor Bechterew in the chair of psychiatry at Leningrad; Professor Rössle, director of the Institute of Pathological Anatomy at Basle, has succeeded Professor Lubarsch in the chair of pathological anatomy in Berlin; Professor Beltzke, the pathologist, has been made rector of the medical faculty of Graz; and Professor von Metternich, the paediatrist, dean of the medical faculty at Frankfort.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR of the *British Medical Journal, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocria Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

EFFICIENT ANTISEPSIS IN MIDWIFERY.

"A." writes: In a recent textbook of midwifery it is stated that in the case of a biniodide solution (1) *soap* precipitates the mercury and so renders this antiseptic useless; and (2) contamination with *blood* renders the mercury solution useless as an antiseptic. I was under the impression that both these statements were true so far as the ordinary perchloride was concerned, but that neither was true in the case of biniodide. I should be glad to have further light on the subject.

OCCASIONAL WEAKENING OR LOSS OF VOICE.

"W. D." asks for advice in treating a strong healthy man, 50 years old, who does a lot of talking in business and finds that his voice seems powerless at times; he does not seem able to raise it without an effort, especially where other people are talking, or in traffic, or when music is being played. It causes him considerable mental worry.

TREATMENT OF CHILBLAINS.

DR. HENRY WALDO (Clifton) writes: Your correspondent (October 19th, p. 744) will concede that prevention is better than cure. This is the view that the late Sir Jonathan Hutchinson took some years ago when he wrote that those who toast their feet never get chilblains.

FLEAS.

"B. C." replying to the request by "W. G. H." (October 19th, p. 744) for a protection against fleas, writes: Years ago I had the same trouble, and I found I could protect myself by the use of Calvert's carbolic and camphor antimosquito soap. I have never tried it against mosquitos, but it certainly seemed to work against fleas.

INJECTION OF THYROID CYSTS.

DR. C. L. MARSH (Yeovil) writes: With reference to the inquiry of "F. S." on October 26th (p. 790) about the treatment of thyroid cysts by injections, I remember when I was at hospital, about fifty years ago, a strong-looking healthy man was admitted with a thyroid cyst about the size of a pigeon's egg. The cyst was injected with tinct. ferri perchlor., and the man was dead in less than an hour. *Verb. sap.*

INCOME TAX.

Sale of Practice.

"E. E. H.," who has usually made up his accounts to April 5th, sold his practice as from June 1st, 1929, and has been asked for a statement of account for the period April 5th to May 31st, 1929. He has no access to the books of his successor.

*** At present we are unable to see that our correspondent would find any particular difficulty in preparing a statement of his receipts and expenses for the two months in question on the basis adopted for the earlier twelve months' accounts. Some such statement, even if estimates of expenses have to be used, will be necessary, because his liability for the financial year 1929-30 cannot be dealt with as a unit, but must be computed separately in respect of his former and his present practice. He should, of course, make sure that the assessment on the latter does not cover a period greater than his ownership of it—presumably ten months only. The inspector of taxes is correct in disallowing "depreciation" if he deducts the cost of renewal of a car.

Residence in the United Kingdom.

"T. C. L." asks whether in the event of an individual arriving in Great Britain from abroad a few days before the end of the financial year (April 5th) with the intention of settling here permanently he is liable to be assessed for the year in which he arrives?

*** Yes, he is so liable, and in respect of foreign income as well as income arising in the United Kingdom. But the amount of the assessable foreign income would be restricted to the amount received in this country, or arising to him after reaching this country, and he would be entitled to the full year's personal allowances from the income assessable for the year of arrival, though that amount would, of course, be less than a year's income. If, therefore, the arrival is "a few days" only before April 5th the liability for the year of arrival would presumably be negligible.

Paying Guest Taken.

"S. S." asks whether and, if so, how the profits on a paying guest are to be entered in the income tax return. The guest pays £5 5s. per week, and costs about 25s. in food, 20s. for firing and lighting, and 10s. for extras, and has the best room in the house.

*** The profit made is assessable. The charge stated above for firing and lighting seems heavy, but, on the other hand, some portion of the total cost of the domestic staff (wages, keep, etc.) is allocable to the amount received from the guest, as well as a *fair portion of the total rent and rates as applicable to* the guest's room. The amount returned will obviously have to be in part based on an estimate, and it looks as if the net amount returnable will be somewhere round about £75 per annum.

LETTERS, NOTES, ETC.

DISCLAIMERS.

DR. F. HOWARD HUMPHRIS (London, W.) writes: Accompanying a prospectus of a company formed, or about to be formed, for treatment centres for electrotherapy, physiotherapy, *x*-ray diagnosis, etc., was a letter said to be addressed to the medical profession. On the back of that letter were two quotations from articles I had written, one in the *Lancet* of March 3rd and the other in the *British Journal of Actinotherapy*. The use of my name is entirely unauthorized, and I have written to the secretary of the company, protesting strongly against the publication of my name without my consent.

DR. J. R. REES (London, W.) writes: A number of stupid, sensational articles appeared in the press at the end of last week with regard to the Tavistock Square Clinic. The inanities of these paragraphs are not worth taking in detail, but, as deputy director of the clinic, may I disclaim the substance almost *in toto*. A reporter came to the clinic and was told a certain amount about the need for the proposed expansion of the work. I saw him myself, and impressed on him that what was needed above all things was restraint, as opposed to sensation, and the series of inventions which appeared in the press were the result.

LIVER INTOXICATIONS.

Corrections.

DR. CHALMERS (Darlington) asks for the following corrections to be made in his letter published in the *Journal* of October 26th at page 786. The sentence beginning in line 9 of the third paragraph should read: "Later, however, it was given as lactate (the chloride at this stage would increase the acidosis)." For the sentence beginning in line 4 of paragraph 4 read: "Alkalis and glucose alone will not save such cases if severe; if my contention is correct that the hypoglycaemia is due to the insulin-like action of guanidin[illegible] to give glucose *plus* insulin." In [illegible] "MacLeod has stated with regar[illegible]g of the parathyroid glands that this may not become evident except at a time of stress, as from pregnancy or improper diet." In the last paragraph, fourth last line, after the word "lines," add: "namely, the use of calcium chloride."

PURIFICATION OF SWIMMING BATH WATER.

DR. F. W. ALEXANDER, formerly M.O.H., Metropolitan Borough of Poplar, writes: Although belated, I greet with pleasure the report of the Ministry of Health on the purification of the water of swimming baths. I regret that no mention has been made of the strenuous, difficult, and prolonged pioneering work carried out at Poplar for over twenty years. "Special reports" were always forwarded, as legally required, to the Ministry of Health.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 48, 49, 52, 53, 54, 55, and 56 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts not filed in the advertisement columns appears in the *Supplement* at page *211*.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

379. Subacute Syphilitic Myocarditis.

INSTEAD of the classical division of syphilitic myocardial lesions into localized and diffuse forms, L. GRAVIER (*Journ. de Méd. de Lyon*, September 20th, 1929, p. 609) classifies them as mechanical (dystrophic) and inflammatory. The first variety, which is due to an obliterating coronaritis, presents no particular characters and is comparatively rare. The inflammatory form may be specific, appearing as gummata, which also are rare, or non-specific (subacute or chronic myocarditis). The subacute form is said to be more directly due to syphilitic infection than the chronic, and presents a more striking clinical picture. A case, diagnosed during life, is recorded which illustrates the principal clinical and anatomical features of this condition. Clinically, subacute syphilitic myocarditis is essentially characterized by a left ventricular insufficiency of sudden onset and progressively rapid evolution, pulmonary oedema being the chief symptom. This type of myocarditis does not occur by itself, as sometimes the tuberculous type does, but is usually accompanied by an aortitis. Gallavardin has especially insisted on this association, and has shown its importance in the evolution of aortic infections. In syphilis is revealed the importance of the inflammatory factor in the pathogeny of asystolic phenomena. Anatomically, subacute myocarditis may present large sclerous lesions, macroscopically visible; more often, however, the lesions are discrete, and discernible only by microscopic examination. They consist of an interstitial connective-tissue reaction, with marked inflammatory characters, which infiltrates the muscular bundles, dissociating the cardiac fibres and forming fibrous bands or areas. The lesions are autonomous; if endarteritis or periarteritis is present, this does not condition the interstitial reaction, but evolves parallel with it. In the recorded case Gravier detected a diffusion of these lesions through the thickness of the muscles, and an absence of electivity, if not of predominance, for the subendocardial layers, the subpericardial fibres being markedly affected. He remarks that there is a great disparity between the grave clinical evolution and the extent of the histological lesions. Gallavardin has also noted this fact, and suggests that other factors may intervene, such as venous influences and reflexes. Gravier considers that parenchymatous troubles may be a causal agent, and should be suspected in certain cardiac or myocardiac hypertrophies with recognizable histological lesions.

330. Epidemic Peripheral Neuraxitis and the Cerebro-spinal Fluid.

ACCORDING to A. BLAIZOT (*Thèse de Paris*, 1929, No. 173) the peripheral forms of epidemic neuraxitis (the term invented by Sicard as being more comprehensive than epidemic encephalitis) comprise numerous clinical types, including an algo-myoclonic form, and types simulating anterior poliomyelitis, spastic paraplegia, Landry's disease, and tabes. The polyneuritis of epidemic neuraxitis usually appears in the form of simple paraplegias or as paraplegias with involvement of the cranial nerves, or quadriplegias. Less extensive lesions may be encountered, involving only the terminal part of the nerves or the muscle only, and giving rise to a pseudo-myopathic form of the disease. In spite of the polymorphous character of these clinical forms, there are numerous arguments in favour of these being due to the same cause—namely, their occurrence during an epidemic, previous history of ocular palsies and lethargy, and transitional pains in the same individual. The disease runs its course with little or no fever; the development of the symptoms is incomplete, and they rapidly and entirely subside. Lastly, the condition of the cerebro-spinal fluid is almost invariably the same; the fluid is clear, under slight pressure, with only slight lymphocytosis, but a considerable increase of albumin. The chlorides are not affected. The Wassermann reaction is always negative, while Guillain's reaction is sometimes positive in the meningeal zone. The thesis contains the histories of four illustrative cases.

331. Clinical Aspects of Influenza.

W. NATORP (*Deut. med. Woch.*, August 16th, 1929, p. 1377) records his observations on 231 cases of influenza admitted to the municipal hospital at Königsberg in January and February, 1929; 151 were women and 80 men. The ages of the patients were usually between 20 and 30. In about two-thirds of the cases there was a sharply circumscribed redness of the soft palate and uvula, as well as of the tonsils and posterior wall of the pharynx, a symptom to which Natorp attaches considerable diagnostic importance. In uncomplicated cases the temperature fell by lysis in two to four days. In about 10 per cent. of the cases the temperature rose again to a subfebrile level at the end of the first or beginning of the second week without any physical signs. The frequently described bradycardia of convalescence was usually absent. Blood pressure estimations, which were made several times a day, showed an average systolic reading of 99–100 mm. of mercury with a tendency to oscillations up to 115 and down to 70. The principal complications were those affecting the respiratory system. Pneumonia occurred in 39 cases, of which 6 were fatal; not infrequently it followed mild attacks. Otitis media was noted in only four cases. Rashes in the form of scarlatiniform and morbilliform eruptions or erythema nodosum were observed in a few cases. A few examples of relapse two to three weeks after the end of the first attacks occurred. Colic was an occasional sequel. Prophylaxis in the form of application of collargol solution to the eyes, nose, and throat was carried out among the nursing staff with encouraging results. The treatment was on the usual lines.

382. Hemiplegia in Scarlet Fever.

J. D. ROLLESTON (*Clin. Journ.*, August 14th, 1929, p. 393), who records an illustrative case, in a boy aged 3½ years, in which cerebral embolism was probably the cause of the condition, states that in 1908 he collected 66 cases of this rare condition, including 3 which he had personally observed. Since then he had found only 9 cases recorded, a total of 75 cases. The ages of the patients ranged from 3 months to 27 years. Though 54 patients had recovered, in only 17 was recovery complete; in most of them contractures had supervened as in the present case. Necropsies had been held on only nine cases, and the most frequent alleged causes were uraemia, and cerebral embolism, thrombosis, or haemorrhage.

383. Primary Mumps Orchitis.

M. A. RABINOWITZ and B. SELIGMAN (*Med. Journ. and Record*, August 21st, 1929, p. 215), who record an illustrative case, state that Wesselhoeft in 1920 collected 64 cases of mumps orchitis in which there had been no parotitis. Their patient was a man, aged 29, who developed pain and swelling of the left testis with fever which lasted for three weeks. The diagnosis was made on the grounds of the absence of gonorrhoea and of instrumental or other trauma; it was ascertained that his daughter had had a mild attack of mumps a fortnight before he became ill.

Surgery.

384. Abdominal Symptoms due to Enlargement of the Mesenteric Glands.

F. BATT (*Nordisk Medicinsk Tidsskrift*, August 31st, 1929, p. 557) records observations made at the communal hospital in Drammen, Norway, during the year July 1st, 1922–June 30th, 1923, and also the year 1926. In the first period appendicectomy was performed on 66 patients under the age of 15, and among these patients there were 19 in whom enlarged mesenteric glands were found (7 boys and 12 girls). In the same period appendicectomy was performed on 336 patients over the age of 15, but only in 2 of them (a boy of 16 and a girl of 18) was a corresponding enlargement of the mesenteric glands observed. In 1926 appendicectomy was performed on 32 patients under the age of 15, and in 16 of these cases the mesenteric glands were found to be enlarged (8 boys and 8 girls). Among these 16 cases there were 5 of chronic and 1 of acute appendicitis. In the remaining 10 cases the operation revealed no evidence of appendicitis. The clinical history of these cases before operation included an acute attack of pain in the abdomen, nausea, vomiting, and more or less fever. On admission to hospital the patients referred their pain to the umbilical region, whence it radiated to the right iliac fossa. But there was no local tenderness or rigidity, deep palpation in the right iliac fossa provoking no pain. Yet on account of the [illegible] of the signs and symptoms of [illegible] deemed advisable to accept [illegible] who had sent the patients to the operation was performed in the acute stage the mesenteric glands were tense and elastic, and there was free serous fluid in the peritoneal cavity. When the operation was performed in the subacute stage the glands were tense and

elastic, but there was no free peritoneal fluid, although the surface of the intestines was remarkably moist. In the eight cases operated on during the free interval, the enlargement of the glands was not so marked; they were not so tense and elastic, and there was no increase of the peritoneal fluid. The microscopical examination of excised glands showed no evidence of tuberculosis or other inflammatory state, but in glands removed during the acute stage there were signs of extensive fat infiltration, which was considerably less marked in the cases operated on in the chronic stage. On the assumption that the capacity of these patients to digest fat was reduced, instruction was given on their discharge that their diet should contain little fat and plenty of carbohydrates. In the spring of 1929 the subsequent fate of these patients was investigated, and information about 14 was obtained. Eight, who at the time of the operation were found to have enlarged glands, but no appendicitis, had sooner or later suffered from recurrences of their symptoms; this was also the case in 3 out of the 6 cases in which acute or chronic appendicitis had been found at the operation. The recurrences in some cases were traced by the parents to fatty meals.

385. Etiology of Dupuytren's Contraction.

DISCUSSING the etiology of Dupuytren's contraction in its relation to the compensation of workmen J. M. DE VILLAVERDE (*La Medicina Ibera*, August 31st, 1929) points out that most cases, though there may be a history of trauma, are really due to some other unknown factor; the patient stresses the injury with a view to compensation. The author cites the case of a carpenter who wounded himself in the left hypothenar eminence with a tool; a year later, although the lesion had long since healed perfectly, signs of Dupuytren's contraction began, but in a few months contraction also appeared in the right hand. Another man received a blow on the arm; the median nerve must have been stimulated, because at the time he felt violent pain over its whole distribution. Some months later Dupuytren's contraction appeared in the same hand, but no signs of nerve involvement were present to support the idea of traumatic neuritis; shortly afterwards the other hand became involved. Many other similar cases are mentioned. The author remarks that investigation of the nervous diseases said to be responsible for Dupuytren's contraction shows that in syringomyelia the deformity that occurs is capable of modification by movement; it is not a fixation as in the genuine Dupuytren's contraction. The same considerations apply to cervical hypertrophic pachymeningitis. In general paralysis the genuine contraction does seem to occur occasionally, but it would be wrong to correlate these as cause and effect; the spirochaete itself can attack all tissues, and might easily be the direct cause of Dupuytren's contraction in these cases. One case only was observed where Dupuytren's contraction coexisted with manifest neuritis; the patient was a coach-painter addicted to alcohol, and in him a definite polyneuritis was a little preceded by Dupuytren's contraction. No other signs of lead poisoning being present, it was concluded that the neuritis was due either to alcohol or to under-nourishment. De Villaverde adds that such neuritis can always be cured by attacking the cause; but in the case cited the contraction persisted in spite of all antineuritic treatment. Moreover, all cases where genuine nervous lesions coëxist with Dupuytren's disease are rare enough to be classed as merely coincidental.

386 Prevention of Aspiration during Tonsillectomy.

UNTIL the inception of local anaesthesia the occurrence of post-operative pulmonary sequels was attributed to the use of an inhalation anaesthetic, but such sequels continued after the introduction of local anaesthetics, and so the relation of inhalation anaesthesia to post-operative pulmonary complications became doubtful. Ample evidence was obtained that pulmonary abscess might follow any surgical procedure, including laparotomy or tonsillectomy. Bronchoscopy and indirect laryngoscopy have been used by all investigators to ascertain the degree of aspiration during tonsillectomy, the operation in which aspiration is most frequent. Thinking that these observations might be erroneous, R. V. MAY, T. W. THORBURN, and H. C. ROSENBERGER (*Journ. Amer. Med. Assoc.*, August 24th, 1929, p. 589) concluded that greater accuracy would result from the use of x rays after rendering the secretions of the throat opaque so that their passage into the lungs might be observed. This procedure was followed in twenty-five patients, whose ages ranged from 3 to 12 years, and who were operated on for the removal of tonsils and adenoids. A mixture of equal parts of sterile olive oil and iodized oil was used to produce opacity of the tracheobronchial tree. These investigations showed that the incidence of aspiration, particularly during tonsillectomy under inhalation anaesthesia, might be diminished by the adoption of the extreme Trendelenburg position; by constant and thorough removal of all pharyngeal secretions; by the choice of those types of anaesthetic and operative technique which cause a minimum amount of mucous secretions and haemorrhage; and by the degree of anaesthesia, which, in part at least, preserves the irritability of the laryngeal and tracheal reflexes. The authors add that the depositing in the lungs of aspirated material is variable and should be further investigated. When aspiration occurs, most or all of the aspirated material is eliminated during the six hours following the operation. Some aspiration is unavoidable in all operations under inhalation anaesthesia, but the technique suggested by the authors reduces this to a minimum.

Therapeutics.

387. Venesection in Congestive Heart Failure.

W. S. MIDDLETON (*Amer. Heart Journ.*, August, 1929, p. 641) has analysed 22 cases of congestive heart failure with the aim of determining the indications for this procedure and its results. The bulk of the patients were suffering from myocardial degeneration, the most prominent etiological factor being arterio-sclerosis. All the subjects except three were males, and 13 of the 22 were over 50 years of age. The level of the venous blood pressure was taken as the principal criterion for venesection. If by the indirect method of Hooker and Eyster a sustained reading of 20 cm. of water was found, and if the usual subjective and objective indications were present, phlebotomy was performed and 50 c.cm. of blood removed. In 11 of the 18 patients who were bled once, and in seven of the eight operations on the remaining 4 patients, the immediate results were favourable. It was found that a fall in venous pressure of 8 cm. of water was usually accompanied by definite clinical improvement. Such a fall occurred in 13 patients, benefit accruing in 11 of them. The ultimate outlook in patients selected for venesection cannot be good, and a survival rate of only 45 per cent. is recorded in the author's group; in an additional 23 per cent. there appeared to be a prolongation of life as a result of the operation, although the recovery was insufficient for discharge from hospital. The five patients who died within thirty-one hours of the operation showed no early amelioration of right heart distress, nor was an adequate venous pressure fall noted; these facts are held to confirm the prognostic importance of such a fall. The series analysed by the author agrees with a series of 21 previously studied by him in point of immediate benefit; as regards ultimate results, the present series shows a more favourable response.

383. Treatment of Gonorrhoea.

W. SCHOLTZ (*Deut. med. Woch.*, August 2nd, 1929, p. 1287) comments on the fact that gonorrhoea in men and women may be cured in a few months without any treatment; this spontaneous cure occurs sometimes in the course of an associated epididymitis. The author suggests that the body has a means of defence which can overcome the infection, and that besides the inflammatory suppurating reaction of the mucous membrane there is an antibody circulating in the blood; this possibility has suggested that a complement-fixation test might serve to indicate the successful termination of the infection after treatment. Without local treatment, however, there is no question that in the majority of cases complications will arise sooner or later and the case will assume a chronic course, the patient remaining infectious for many years. For local treatment Scholtz recommends Neisser's antiseptic methods of injections of silver salts. He gives five injections daily for four to seven minutes, slowly increasing the concentration of protargol from 0.3 to 2 per cent. solution, and usually succeeds in removing the gonococci in one to three days. The silver preparation acts directly on the superficially situated gonococci, but besides this there is a tissue reaction, an effect of the injection on the mucous membrane. This tissue reaction results in the production of "silver pus," which is composed more or less of degenerated and badly staining pus cells, in contrast to gonorrhoeal pus, which is characterized by the presence of healthy leucocytes with well-stained nuclei. In gonorrhoeal pus gonococci are always present, but in "silver pus" cocci are rarely found. The production of "silver pus" is therefore an indication of successful treatment. The injections are continued daily until the preparations from the discharge have been free from gonococci for more than three weeks. The difficulty of determining whether a patient is cured is well known; for this there are no certain criteria apart from the absence of gonococci and the presence of "silver pus." Scholtz thinks that the complement-fixation test, which seemed likely to be helpful in this respect, needs further research. As now applied it occasionally gives non-specific reactions; sometimes the reaction is permanent with gonorrhoeal complications, and can remain positive for months,

even a year, after the gonorrhoea has been completely cured. A positive result after completion of treatment is therefore of little value, but a negative reaction following a positive reaction seems of great use in the confirmation of cure.

389. Extra-diabetic Indications for Insulin.

J. HOET (*Bruxelles-Médical*, September 8th, 1929, p. 1243) calls attention to certain non-diabetic affections where insulin has been found very beneficial. Its use is based on its power to increase hepatic glycogen, to lessen the formation of acetone bodies, and to restore a normal protein metabolism. In the vomiting of pregnancy, when insulin is given in full doses (10 to 40 units) in association with a diet rich in carbohydrates and glucose, excellent results have been obtained; so also is the case in post-anaesthetic vomiting. In children cyclic vomiting accompanied by acetonuria is often relieved by insulin, and the same is true of certain chronic affections of the skin, such as boils, chronic ulcer of the leg, and pruritus. In arteritis obliterans, hypertension, or angina the results are not so favourable. Lastly, the author comments on the good results which often follow the administration of insulin in states of denutrition and wasting.

Dermatology.

390. A Hereditary Ectodermal Dystrophy.

H. R. CLOUSTON (*Canadian Med. Assoc. Journ.*, July, 1929, p. 18) presents an analysis of 119 cases in six generations, 40 of which were inspected, of a well-marked and easily recognized condition, usually known as hereditary or familial dystrophy of the hair and nails. The disease, though very rare, as judged by the scanty references to it in medical literature, is said to be comparatively common in eastern Canada, where it is peculiarly associated with the French race. Both sexes are equally affected, transmit it equally, and one-half of the children of defectives of this kind are defective. The dystrophy, therefore, follows the law of Mendelian hybrids, not sex-linked, the defect being a dominant. The dystrophy involves the epidermis itself, the nails, hair, sebaceous glands, and to some extent the sweat glands. Dystrophy of the nails is a constant factor, and the nail defect is more persistent than that of the hair. The toe-nails are always affected when the finger-nails are involved. Scrapings have proved negative for mycoses. The hair condition is a true and general hypotrichosis persisting from birth, and is a failure of the pilo-sebaceous system to develop. Microscopical examination shows only a fine hair which is otherwise normal. The condition of the eyebrows is a most striking feature; they are thinned, often markedly, in their outer two-thirds, as contrasted with the thinning of the outer third in hyperthyroidism. The skin dystrophy varies greatly, and is present in those spots where the stratum lucidum is present—as, for example, the palms of the hands and the soles of the feet. Clinical evidence is presented that the condition involves other ectodermal tissues, such as the teeth, the nervous system, and the glands of internal secretion of ectodermal origin. Involvement of the suprarenal medulla is suspected because the symptoms resemble those of Addison's disease in its earlier stages. Involvement of the anterior lobe of the pituitary gland is held to be responsible for certain features suggestive of those found in acromegaly. Since the condition is as fundamental as the germ plasm, the treatment is necessarily familial rather than individual. The dystrophy tends to diminish in succeeding generations, both as to incidence and severity, and every transitional stage is seen. Familial dystrophy of the nails alone may be a mild expression of the same condition. Hereditary keratosis plantaris et palmaris, in certain cases, is probably another residual form of the disappearing dystrophy.

391. Sulphur Baths in Dermatology.

A. E. OSTERBERG, M. W. RUBENSTEIN, and W. H. GOECKERMAN (*Arch. Derm. and Syph.*, August, 1929, p. 158) remark that sulphur and its compounds as they occur in natural waters and also in artificial sulphur baths have a beneficial effect when combined with other types of treatment for skin diseases. In order to ascertain the reasons for the efficacy of sulphur, these authors decided to determine first whether there was any absorption of sulphur compounds by the blood, and, if this did occur, where it took place, the effect of the type of sulphur employed on its rate of absorption, and whether there was any relation between the results obtained, the type of sulphur, and its concentration in the blood. Accordingly the total concentration of sulphur in the blood and the total amount excreted in the urine were determined in sixteen patients with various pathological skin conditions, and in two without cutaneous lesions on whom had been imposed a therapeutic regimen which included some form of sulphur baths. All the patients received the usual hospital diet, the sulphur content of which was equivalent to that of a well-balanced normal diet. The baths were given daily over varying periods, and three types were used, one of which contained colloidal sulphur. The data from these experiments lead to the conclusion that considerable sulphur is absorbed when a bath is prepared in such a way that sulphur dioxide is evolved. If the influence of sulphur dioxide is eliminated, either by arranging that the patient shall breathe through a gas-mask or by preparing a bath containing only colloidal sulphur, the rise in the concentration of sulphur in the blood or the total amount of sulphur excreted is much less marked, although the therapeutic response is as good. The authors believe that sulphur baths are a valuable adjunct in dermatological therapy, but that the mechanism of their action is unknown. Their greatest efficiency appears to be in diseases of vesicular and pustular types.

392. Treatment of Sycosis Barbae.

E. P. FIDANZA (*Ann. de Derm. et de Syph.*, July, 1929, p. 731) reports seven cases of trichophytic suppuration of the beard treated by him with preparations of iodine. The first five patients were given intravenous injections of from 2 to 5 c.cm. of Gram's iodine solution diluted with from 5 to 15 c.cm. of physiological serum. Improvement ensued in all cases, but treatment had to be discontinued temporarily in four owing to the occurrence of induration and obliteration of the veins, with much discomfort. After an interval treatment was continued and completed. The last two cases, however, were treated with a 20 per cent. solution of the biniodide of hexamethyl diamino-propanol, which was given daily by the intravenous route; improvement was rapid and the cure was complete. The drug was well borne and there was neither malaise nor local trouble. Fidanza thinks that the iodine acts on the lymphoid tissue, causing a lymphocytosis, rather than directly on the parasite. The preparation used contains 0.18 gram of iodine per c.cm. in combination with nitrogen, which raises its tolerability and assures its regular disintegration—an advantage over the carbon combination. The author advises a daily administration of 2 c.cm., which dose has given him the best results. Sporotrichosis, actinomycosis, and blastomycosis are mentioned as diseases in which this treatment might be accompanied by similar satisfactory results.

393. The Etiology of Eczema.

A SERIES of experiments has led Dr. J. TRÉGER (*Bratislavské Lékárske Listy*, August, 1929, p. 551) to the conclusion that various substances are capable of producing eczema on the human skin. The particular reaction of the skin in each individual case is independent of the chemical constitution of the irritating substance, and in the same person several different chemical substances can produce similar eczematous lesions. The character of the reaction depends entirely on the specific reactivity of the skin concerned. The possibility of transmitting eczema by means of the blood serum from an eczematous person has not been proved, but it is possible to transmit urticaria and exanthemata caused by drugs (such as salvarsan exanthema) by means of serum collected from spontaneous or artificial blisters formed on the skin of the affected person. It is also possible to transmit the reactivity to certain chemical substances from patients with pemphigus or dermatitis herpetiformis to other persons, but these other persons reacted no more definitely with pemphigus or this dermatitis than with eczema.

Obstetrics and Gynaecology.

394. Indications for Myomectomy.

R. H. HARRIS (*Surg., Gynecol. and Obstet.*, September, 1929, p. 322) summarizes the relations between fibromyoma of the uterus and pregnancy, and gives statistics of the removal of fibromyomata in 147 cases, with detailed reports in five. Although pregnancy and labour may progress satisfactorily in the presence of a large uterine fibromyoma, this condition may give rise to serious complications in pregnancy, labour, and the puerperium—such as uterine haemorrhages, breech and transverse foetal positions, high foetal mortality, stasis in the urinary and intestinal tracts, and sepsis. The presence of such tumours may prevent pregnancy by obstructing the cervix or uterine cavity, and by changing the glandular and vascular structure of the endometrium; but in examining statistics of sterility caused thereby such factors as refusal to bear children, widowhood, the menopause, and diseases of the adnexa must be considered. Diagnosis may be difficult when early pregnancy exists in a fibromyomatous uterus, or when a large soft fibromyoma simulates pregnancy. In

women under the age of 40 who are desirous of having children, but who are sterile owing to fibroids, pregnancy frequently follows myomectomy; such patients should, however, be selected carefully, the surgeon reserving the right to perform hysterectomy should its need be indicated by the discovery of conditions such as malignancy and disease of the adnexa. Myomectomy during pregnancy may be necessary because of degeneration, torsion, impaction, or magnitude of the fibromyomata; hysterectomy is rarely needed unless it is found that the patient cannot be saved by myomectomy from accidents due to the tumour, or that infection or malignancy is present.

395. FROM a detailed study of myomectomy unassociated with pregnancy, E. MERIEL and BAILLAT (*Gynecol. et Obstét.*, August, 1929, p. 223) conclude that this operation should be performed only in the young with a view to future maternity, and that, in these cases, it is for this reason preferable to hysterectomy or irradiation. The danger from shock, haemorrhage, infection, or embolism is no greater than in hysterectomy, and the mortality in the two procedures is the same. Though after this operation the tumours are liable to recur, these new fibroid growths rarely undergo malignant degeneration, and, since they recur only about ten years after surgical intervention, the patient is assured of that period of normal genital life. The indications for myomectomy depend on the nature, size, and number of the growths. In soft tumours invading a great portion of the uterine walls, in very large tumours, and in multiple fibromas (exceeding two to four in number) hysterectomy is to be preferred. A. BRINDEAU (ibid., p. 235) agrees that myomectomy in non-pregnant women does not prevent future gestations, and that these evolve normally and without complications. Even when fibromas exist, pregnancy usually terminates normally. In certain cases with such symptoms as violent pains, rapid hypertrophy of the tumour, and torsion of the pedicle, surgical intervention is indicated. In the majority of these myomectomy can be performed with excellent results both for the mother and child. This operation is less frequently indicated during labour, since fibroma praevia at the end of pregnancy is rare. It should only be performed after extraction of the infant by Caesarean section. If myomectomy is then found impossible or dangerous, hysterectomy should be performed. Vaginal myomectomy is rarely indicated, and then only in cases of submucous tumours causing an obstruction in the cervical orifice.

396. Thyroid Treatment in Eclampsia and Pre-eclampsia.

G. GROSSI (*Ann. di Ostet. e Ginecol.*, August, 1929, p. 1019) describes eight cases of pregnancy or puerperal eclampsia and fourteen cases of pre-eclampsia with high degrees of albuminuria, in which the daily administration of 70 to 100 drops of thyroid extract was followed by speedy cessation of any convulsions and albuminuria, and rapid fall of the blood pressure. The dietetic regime was of the ordinary character, and no purgative or depleting treatment was employed. The efficacy of the thyroid medication is ascribed to (1) the fact that thyroid hypofunction accompanies many cases of pregnancy albuminuria; (2) a vasomotor action on the kidneys which favours diuresis; and (3) the increased excretion of chlorides.

397. Diathermy in Gynaecology.

F. A. MAGUIRE (*Med. Journ. of Australia*, July 13th, 1929, p. 38) discusses the application of diathermy in gynaecology. Surgical diathermy, by means of which the heat is concentrated by the active electrode over the small area to be treated, with the indifferent electrode placed evenly in contact with a large area of the body well removed from the site of operation, may be used with advantage in the treatment of cervical erosion, caruncles, malignant disease, or gonorrhoeal infection of the cervix, vagina, or urethra, salpingitis, and in such joint affections as chronic arthritis or osteo-arthritis. Erosions of the cervix heal rapidly if they are lightly touched with a small disc electrode and are then allowed to coagulate to a depth of 2 to 3 millimetres; urethral caruncles can be completely and painlessly removed and their recurrence prevented. Most useful in malignant conditions, the treatment arrests haemorrhage, destroys secondary pathogenic infection and the septic portions of the growth, reduces glandular enlargement, allows a clear operating field, and affords a means whereby many inoperable growths can be made operable. In gonorrhoeal conditions the gonococci are killed for a distance of from 10 to 15 millimetres from the lumen of the canal by temperatures of 110° to 115°F., no organisms being found by microscopical examination after a month's treatment. Diathermy is used in salpingitis to produce a general heating of the pelvic organs, for the relief of pain and effusions, and as an accessory to douching. Local diathermy of the joint in chronic arthritis, either inflammatory or gonococcal, relieves pain and inflammation, and promotes absorption; in gonorrhoeal arthritis excellent results have followed its use in combination with local urethral or cervical treatment. Three to five applications over the sacro-iliac joints in chronic arthritis in elderly women have often afforded complete relief, especially in those cases in which *x*-ray examinations indicate definite bony changes.

Pathology.

398. Blood Cells of the Newly Born.

C. E. FORKNER (*Bull. Johns Hopkins Hospital*, August, 1929, p. 75) has examined the blood of children over a period of twelve days from the day of birth; he used an *intra vitam* method of staining with 0.5 per cent. neutral red and 0.1 per cent. Janus green in 95 per cent. alcohol. On the first day the total number of white cells ranged from 15,250 to 45,000 per c.mm.; it fell more or less precipitately on the second day, reaching 10,000 by the fifth to sixth day. The polymorphonuclear leucocytes decreased in percentage and in absolute numbers during these first days, the lymphocytes gradually increasing in percentage and in absolute numbers: eosinophil leucocytes averaged 2.07 per cent. on the first day and 3.42 per cent. on the tenth day, the absolute numbers of these cells remaining constant between 400 and 600 per c.mm. The monocytes ranged from 1,400 to 2,200 per c.mm., which is high; these cells did not share in the initial decrease of the total white cells, and followed neither the lymphoid nor the myeloid elements in their fluctuations. The number of neutrophil myelocytes and reticulated red cells was high on the first day, but rapidly decreased. The average total number of red cells decreased until the fourth day from 5,963,000 to 5,497,000, with a slight rise at the end of the first week, and subsequently falling slightly to 5,252,000 on the tenth day. The total number of platelets averaged 350,460 per c.mm., with a slight drop by the tenth day.

399. Physiology of the Sexual Hormones.

BY injections into castrated mice E. PHILIPP (*Zentralbl. f. Gynäk.*, September 21st, 1929, p. 2386) has found that the sexual hormone folliculin or oestrin is contained in large amounts in the urine of newborn infants of either sex until the end of the third day. The blood of the umbilical vein has previously been shown to contain the hormone. A number of observations are described which show that the source of the hormone in the newborn is the placenta: (1) it is present in hydatiform mole, which is purely foetal; (2) in the sow towards term the maternal ovary and blood, as well as the maternal portion of the placenta, contain practically none of the hormone concerned, while it is abundantly present in the foetal part of the placenta, the liquor amnii, and the foetal blood; (3) in the rabbit the oestrogenous substance is first detected in the blood towards term. It is well known that the hormone is abundant in the human placenta, and the author points out that the name "folliculin" in this connexion is inappropriate; the placenta plays the most important part in its production. It was also found that the urine of infants one to ten days old injected into infantile mice brought about the hypertrophic and intein changes in the ovarian follicles which are ascribed by Zondek and Aschheim to action of the anterior pituitary hormone, and constitute the criterion in their test for pregnancy by examination of maternal urine. Philipp confirms the observation also of Zondek and Aschheim that placental implantations induce similar ovarian changes in infantile mice; he found that particles of hydatidiform mole implanted, or the vesicular fluid injected, were also effective, and that the "anterior pituitary hormone" was more abundant in the foetal than in the maternal portion of the sow's placenta. He concludes that the pregnancy reaction of Zondek and Aschheim is due less to an overproduction of hormone by the anterior lobe of the pituitary than to a new production of hormone by foetal tissues.

400. Persistence of Meningococci after Death.

H. WILLIAMS, R. VAN WOERT, and V. M. BERGSTROM (*Journ. Amer. Med. Assoc.*, August 10th, 1929, p. 437) record a case in which live meningococci were isolated from the spinal fluid taken post mortem from a girl aged 8 years. The child had died on the fourth day of illness, and lumbar puncture was made to exclude the diagnosis of poliomyelitis. The body had been embalmed by the cavity process for twenty-six hours when the lumbar puncture was made, and thirty hours had elapsed from the time of death until the spinal fluid was examined. The meningococci did not belong to any particular type, but agglutinated polyvalent antimeningococcal

DOCTORS THEMSELVES *PRAISE* "RYVITA CRISPBREAD"

Dr. . . . . Harley Street, W.1.—"I am already using and prescribing 'RYVITA,' and I think it excellent."

Dr. . . . . S.W.1—"This product solves the question—the importance of which has recently been brought into such prominent notice:—viz., of finding a wholemeal bread, pleasant to the taste, and demanding thorough mastication."

Dr. . . . . Ledbury.—"Please send 10 lbs. of 'RYVITA.' Everyone prefers the 'RYVITA' to bread. It is far superior from the point of view of health."

Dr. . . . . Bournemouth.—"Am delighted with your 'RYVITA.' Please send me a further 7 lbs."

Dr. . . . . Yeovil.—". . . . I have recommended 'RYVITA' to a large number of my patients, who are highly delighted with it."

Dr. . . . . Crewkerne.—". . . Up to now I think I have consumed personally about 30 lbs. of 'RYVITA.' My boys love it; scores of my patients are eating it."

Dr. . . . . Glasgow—". . . Many ask about 'RYVITA'; we use nothing else, and always have it on the table for visitors' use as some, like ourselves, are already very fond of it. It is exceptionally good for keeping the gums and teeth in a sound healthy condition. The salivary glands are also stimulated to function in a normal and healthy manner; contributing further to a sound state of oral hygiene. I will be glad to recommend 'RYVITA,' and wish you and your Company every prosperity."

Dr. . . . . Droitwich.—"Kindly send me another 10 lbs. It is the very thing I have been looking for, for years. My household like it very much."

. . . . . Esq. (Dentist), Wimpole Street, W.—"I shall be pleased to recommend 'RYVITA' to my patients, especially for children's use."

Dr. . . . . Eastbourne.—"Very delicious to eat."

"*Dr. . . . . S.W.1*, has recommended and distributed several packages to patients of supply he purchased last week, and would be glad of samples for this purpose."

Dr. . . . . Almondsbury.—"I am exceedingly pleased with 'RYVITA,' and personally I have been freer from indigestion while taking it than for many months; consequently, I am recommending it freely in my practice. Send me a supply of samples to give to my patients. I have given several patients some of my own stock to start on."

Dr. . . . . Southport.—"Have already induced a number of my patients to use 'RYVITA.' In cases where there has been habitual constipation, the result of eating 'RYVITA' has been excellent and the constipation has yielded without the use of aperients. You cannot make 'RYVITA' too widely known."

(Later letters.)

"I have nothing but good to report regarding 'RYVITA CRISPBREAD.' It has been excellent in all cases of constipation. Send me about 25 booklets, also a sample of 'RYVITA' to patient at address below."

"Some little time ago you brought 'RYVITA' to my notice. I got a large number of my patients to take it regularly. Some of these have been supplied in shops with 'something just as good.' Some are now buying an article which to my mind and experience is not as good as 'RYVITA.' There should not be this risk of their having something else palmed off on the customers."

NOTE.—The originals of all the above letters, are, of course, available, and can be seen by any persons properly interested.

(We could fill many pages with similar letters from Medical Men.)

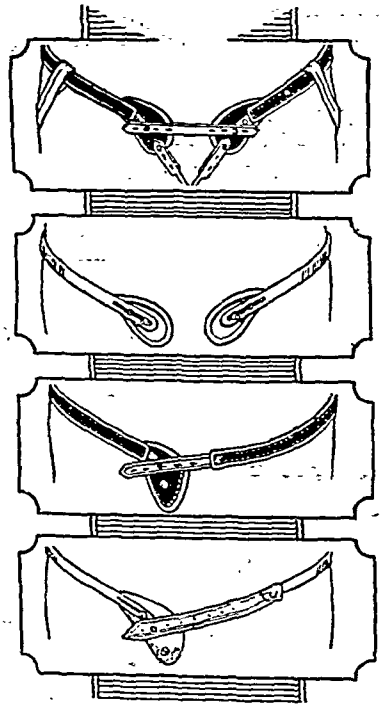
with the aid of
Salt's Surgical Service
CAN
(except in cases of gross carelessness on the Patient's part)
PREVENT
future cases of
SEVERE HERNIA
and greatly alleviate
those already existing.



EFFICIENT TRUSSES BY POST

In many instances the Medical Man is faced with the impossibility of sending his patient to a skilled Truss Maker on the grounds of ill health, absence from employment, or cost of travelling.

Saltair Surgical Service has overcome this difficulty by fitting a patient with an "**Efficient Truss**" to his own doctor's prescription.

The special order forms we supply give us sufficient information, even in difficult or abnormal cases, to supply a spring of correct strength and shape, to cover and pad it as required, and to fit an adjustable pad of the correct size and shape. Hence, we supply by post to the doctor a Truss which is an accurate interpretation of his prescription.

Now available for every Hospital.

The acme of Simplicity.

The NINETY-THIRTY **X-RAY APPARATUS**

Certified by NATIONAL PHYSICAL LABORATORIES as complying with RECOMMENDATIONS OF THE X-RAY COMMITTEE ON PROTECTION.

The power of the apparatus here shown is 90 kilo-volts at 30 milliamperes and is therefore capable of meeting the requirements of any hospital for diagnostic radiography and fluoroscopy.

The floor space occupied by the complete installation is only 9 ft. × 2 ft. and is therefore suitable for any X-ray room.

The operation of the outfit is so simple that any doctor can obtain radiograms of first-class quality even though he may have had no previous experience. The difficulties associated with X-ray work in the past are now entirely overcome by a device known as the "Automatic Technique Director" which indicates the exact setting of the controls for radiographing any part of the body. The outfit includes a full set of accessories, dark room equipment, etc., and thus COMPRISES A COMPLETE INSTALLATION.

PRICE complete, as illustrated, for use on Alternating Current, including all Accessories **£350**

Ditto, Apparatus for use on Direct Current **£410**

The outfit can be supplied with Metalix X-Ray tube instead of Coolidge X-Ray tube at an additional charge of £10.

"Tailoring to Tradition"

By Appointment to H.M. the King and to H.R.H. the Prince of Wales.

The S.B. "SANDHURST" as illustrated is tailored in all-wool weatherproof Aquascutum cloth; also in exclusive Tweeds and Covert Coatings, from 6 guineas, ready to wear or to order. Greatcoats in "Eiderscutum," Lambswool Fleeces, and Camel Hair from 9 guineas. "Field" Coats 3½ to 5 gns.

An Appreciation—

"I may say the coat is everything that could be expected, and here, in the North of Ireland where we have generally cold winds and rain, it really 'keeps the life in one.' I could not desire a better garment, and I question if it would be possible to obtain any for all-round purposes such as my Aquascutum. It has been admired everywhere I go, and I am continually going from place to place in discharge of my duties. . . . ."

Please write for Folder "C" which illustrates other new 'Scutum Greatcoats.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the sea-shore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

titioners
PUBLIC

The duties embrace the charge of the Government Public Health Department, which controls the Medical, Nursing, and Hospital Services; Medical and Dental Services for Schools, Defence, and Police; Health on Mines; Registration of Births and Deaths; Administration of Law Ordinances relating to Public Health, Foods and Drugs, Medical and Dental Registration, Leprosy Repression; Lunacy; and the Department generally deals in an advisory capacity to the Government in all matters pertaining to the Public Health.

The appointment to be subject to six months' notice of termination by either side. The appointment is on the Pensionable Establishment of the Southern Rhodesia Civil Service.

Applicants must also possess a recognized Diploma in Public Health and must be able to assume duty by April 1st, 1930. Salary will be at the rate of £1,750 per annum, with an allowance of £120 per annum towards the cost of motor transport at headquarters.

First-class steamship and rail passage to Salisbury will be provided.

Private practice will not be allowed.

Further particulars can be obtained from the Secretary, Office of the High Commissioner for S. Rhodesia, Crown House, Aldwych, London, W.C.2, to whom applications, with full details as to age, qualifications, past appointments held, with references, etc., should be addressed and should reach that official not later than November 15th, 1929.

County Borough of Dewsbury.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER.

The Dewsbury Corporation invite applications from duly qualified and registered Medical Practitioners holding the Diploma in Public Health for the position of Medical Officer of Health and School Medical Officer at a commencing salary of £900 per annum.

The gentleman appointed will be required to devote the whole of his time to the duties of the office, to reside in the Borough, and will not be allowed to engage in private practice. All emoluments or fees which may be payable to or received by him, must be paid over to the Corporation.

The appointment will be made in accordance with and subject to the Public Health Officers Act, 1921, the Sanitary Officers Order, 1926, and to the approval of the Minister of Health.

Canvassing, either directly or indirectly, is prohibited. Applicants may, if they desire, forward 15 copies of their application and testimonials for the use of the members of the Committee.

Applications, with copies of not more than three recent testimonials attached, to be sent to me, endorsed "Medical Officer of Health," not later than November 8th.

Town Hall, HOLLAND BOOTH,
Dewsbury. Town Clerk.
October 18th, 1929.

Borough of Dover.

ASSISTANT MEDICAL OFFICER OF HEALTH.

The Corporation of Dover invite applications for the above appointment from Medical Practitioners between 30 and 40 years of age who hold a Diploma in Sanitary Science. Salary £700, rising to £750.

The applicant appointed will be required to commence his duties as soon as possible and to devote his attention principally to work under the Aliens Order, 1920. Colloquial French and German will be a recommendation.

Further details of the duties and terms and conditions of the appointment may be obtained of the undersigned, to whom applications, accompanied by copies of testimonials, must be delivered by November 7th.

Town Clerk's Office, R. E. KNOCKER,
Brook House, Town Clerk.

Last day for applications November 11th.

28 Mawdsley St., H. I. COOPER,
Bolton. Clerk to the Guardians.
October 18th, 1929.

County Borough of Derby.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH.

The Council of the County Borough of Derby invite applications for the appointment of Medical Officer of Health for the Borough. Commencing salary £1,100 per annum.

Candidates must be duly qualified Medical Practitioners possessing a recognized Diploma of Public Health and the requisite qualifications required by Acts of Parliament and Regulations of the Ministry of Health. Any applicant appointed must devote the whole of his time to his duties and not engage in private practice.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and the selected candidate will be required to pass a medical examination satisfactory to the Corporation.

Age not to exceed 40 years in the case of any applicant not already in the service of the Corporation.

Other conditions being equal, preference will be given to applicants possessing the necessary qualifications who have actually served in the Forces overseas.

Particulars of qualifications and duties of the office and terms and conditions of service, together with forms of application, may be obtained from the undersigned, and applications endorsed "Medical Officer of Health" (on the form supplied only), accompanied by copies of not more than three recent testimonials, to be sent to the Town Clerk, Derby, not later than Saturday, November 16th.

Canvassing, either directly or indirectly, will be a disqualification.

Market Place, G. TREVELYAN LEE,
Derby. Town Clerk.
October 30th, 1929.

County Borough of East Ham.

MEDICAL
RESIDENT
ISOLATION

The Town Council invite applications from duly qualified persons for the appointment of Deputy Medical Officer of Health and Resident Medical Superintendent of the Isolation Hospital at a salary of £700 per annum, plus residence, light, and fuel (these emoluments being valued for superannuation purposes at £100 per annum).

Age not to exceed 45 years.

The successful candidate will be required to give full-time service and act under the control and direction of the Medical Officer of Health. Administrative and organising ability are essential qualifications for the post.

Candidates must possess the Diploma in Public Health and must have had previous experience of administration in a Public Health Department of a Municipal Corporation.

The appointment will be subject to the approval of the Ministry of Health and the Board of Education.

The person appointed must not engage in private practice, and will be required to pass a medical examination, and the appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Applications, on forms to be obtained from the undersigned, must be, together with copies of three recent testimonials, received by him on or before noon on Thursday, November 14th.

Canvassing, either directly or indirectly, will disqualify.

By Order,
Town Hall, C. EUSTACE WILSON,
East Ham, E.6. Town Clerk.
October 16th, 1929.

J. A. BEARDSALL, Secretary-Supt.

Bootle Borough Hospital.
APPOINTMENT OF HONORARY SURGEON.

Applications are invited from gentlemen for the above vacancy.

Candidates are requested to send particulars of their qualifications, accompanied by testimonials, addressed to the undersigned, not later than Friday, November 15th.

J. A. BEARDSALL, Secretary-Supt.

Holborn Union, London.

TO MEDICAL PRACTITIONERS.

The Guardians of the Poor of the Holborn Union require the services of a Medical Practitioner or Practitioners as DISTRICT MEDICAL OFFICER for the Holborn District, MEDICAL OFFICER for the Receiving Home for Children, Lloyd Street, W.C.1, and PUBLIC VACCINATOR for the Holborn (Western) District of the Union. The salary for the office of District Medical Officer is £120 per annum and for the Receiving Home £15 per annum, subject to deductions under the provisions of the Poor Law Officers Superannuation Act, 1896; the fees receivable as Public Vaccinator amount approximately to £20 per annum.

The gentleman to be appointed must reside within the respective districts or so contiguous thereto as to occasion no inconvenience in the performance of the duties. The District Medical Officer will be required to attend at the Administrative Offices, 53, Clerkenwell Road, E.C.1, one hour each day—viz., from 9 to 10 o'clock a.m. He will also have to visit applicants for medical relief at their houses at any hour on receipt of a Relieving Officer's Order.

All medicines, etc., are provided by the Guardians.

The appointments are subject to the sanction of the Minister of Health and the provisions of the Local Government Act, 1929.

Applications, stating qualifications and full particulars, should be made in the form of a letter, accompanied by not more than three testimonials, addressed to the undersigned not later than noon on Monday, November 11th.

Selected candidates will have notice when to attend before the Guardians.

By Order,
Administrative Offices, 53, Clerkenwell Road, E.C.1. CHAS. J. CROSS, Clerk to the Guardians.
October 26th, 1929.

County Borough of Southampton

RESIDENT MEDICAL OFFICER.

The Corporation invite applications for the position of Resident Medical Officer at the Borough Isolation Hospital.

The gentleman appointed will hold office during the pleasure of the Council, will be required to reside at the Isolation Hospital, to devote his whole time to the duties of the office, and to act under the direction of the Medical Officer of Health.

Salary £350 per annum, with residence, board, and washing.

The Local Government and Other Officers Superannuation Act, 1922, will be applicable to the appointment, and contributions to the Superannuation Fund will be deducted from the salary. The selected candidate will be required to pass a satisfactory medical examination.

Forms of application may be obtained from the Medical Officer of Health, Municipal Offices, Southampton.

Applications on the prescribed form, endorsed "Resident Medical Officer," and stating age, qualifications, experience, etc., together with copies of not more than three recent testimonials, must be delivered at the Town Clerk's Office, Municipal Offices, Southampton, on or before November 16th.

R. RONALD H. MEGGESON,
October 25th, 1929. Town Clerk.

County of London.

The LONDON COUNTY COUNCIL invites applications for appointment as EIGHTH ASSISTANT MEDICAL OFFICER (man) in its Mental Hospital Service. Candidates must be under 35 years of age and be registered to practise both in Medicine and Surgery in England. Salary £300 a year, rising by annual increments of £25 to £400 a year, plus fluctuating temporary additions, the present total commencing remuneration being approximately £493 a year. No emoluments. Charges made for board, lodging, etc. (at present £2 9s. weekly) if required to be resident. Candidate appointed will be pensionable under the Asylums Officers Superannuation Act, 1909. Form of application, on which full particulars are given, can be obtained from the Acting Chief Officer, Mental Hospitals Department, The County Hall, Westminster Bridge, S.E.1. Completed applications must be received by Thursday, November 14th. Canvassing disqualifies.

MONTAGU H. COX,
Clerk of the London County Council.

Batley and District Hospital.

(General Hospital. 84 Beds.)

Wanted, RESIDENT HOUSE SURGEON, fully qualified (male). Salary £150 per annum, with board, residence, and laundry.

Applications, stating age, qualifications, and copies of testimonials, should be sent to the undersigned at once.

Batley, Yorks. A. W. WESTERN, Secretary.

City of Manchester.

APPOINTMENT OF ASSISTANT TUBERCULOSIS OFFICER.

The Public Health Committee invites applications for the position of Assistant Tuberculosis Officer at a commencing salary of £650 per annum, rising by annual increments of £25 to £750 per annum. (First increment January 1st, 1931.)

Candidates must be fully qualified Medical Practitioners having special knowledge of Medical and Surgical Tuberculosis. Candidates should state whether they possess the Diploma of Public Health.

Applications, stating age, qualifications, and experience, with copies of not more than three recent testimonials, and endorsed on the envelope "Assistant Tuberculosis Officer," must be addressed to the Town Clerk only, and not to members of the Committee or Council, and must be received by him not later than Monday, November 18th.

The gentleman appointed will be under the administrative control of the Medical Officer of Health and the immediate control of the Senior Tuberculosis Officer. He will be required to devote the whole of his time to the duties of his position, to execute the Deed of Service, and to contribute to the Corporation Superannuation Fund.

Canvassing in any form, oral or written, direct or indirect, is prohibited.

By Order,
Town Hall, Manchester. F. E. WARBRECK HOWELL, Town Clerk.

The Radium Institute,

Riding House Street, London, W.1.

Applications are invited from duly qualified Medical Practitioners for the post of WHOLE-TIME ASSISTANT (non-resident) in the MEDICAL DEPARTMENT of the Institute.

The salary will be at the rate of £600 per annum, and the appointment will take effect as from January 1st, 1930.

The present House Surgeon is a candidate for the post.

Applications, stating age, qualifications, and experience, with copies of three recent testimonials, must be received at the Institute not later than November 12th.

Canvassing, either directly or indirectly, is not permitted.

THOS. A. GARNER, Secretary.

Ministry of Pensions.

BIRMINGHAM PENSIONS HOSPITAL COMMITTEE.

HIGHBURY HOSPITAL, BIRMINGHAM.
(144 Beds.)

Applications are invited for the post of RESIDENT MEDICAL OFFICER at the above Hospital.

The cases treated are Surgical (mainly Orthopædic) and Medical, but the duties required of the successful candidate will be mainly Surgical.

Salary £350—£400 per annum, according to experience, with lodging, fuel, and light. The appointed candidate to be prepared to take up duty on or about November 26th next.

Candidates selected for interview will be required to pay their travelling expenses.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)

(FOUNDED 1880.)

12, Stratford Place, Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London. Telephone: Mayfair {1782 1785

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work - i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

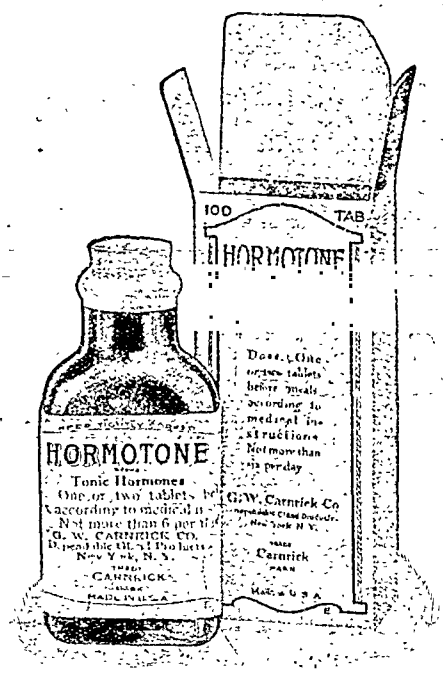
AMENORRHEA
DYSMENORRHEA

"It is a very great mistake to treat amenorrhea as though it were simply a lack of the catamenia, for it is a great deal more than that. Behind this lack lies a cause. It may be in the uterus or the ovaries, or it may be still farther back in the secretions of the endocrine glands or in the functioning of the vegetative nervous system."—("The Treatment of Amenorrhea," Dalché, *Revue Française de Gynecologie et d'Obstetrique*, May 1, 1920.)



In the treatment of irregularities of the catamenia, rational therapeutic procedure is directed to the restoration of normal balance in the endocrine and vegetative nervous systems.

Hormotone
BRAND

contains thyroid, pituitary, adrenal, and gonad substance, combined to take advantage of the demonstrated synergism existing between them. In the treatment of these disorders Hormotone has been very successful.

Dose: One or two tablets three times daily.

DIABETES AND AUTO-TOXINS

Though the introduction of Insulin is one of the great events of [illegible] both the incidence and [illegible] remain at levels incomp[illegible] a truly curative agent has been found. Diet and the effective elimination of normal and abnormal auto-toxins still demand the attention of the clinician, every bit as much as in pre-insulin days. It is peculiarly important in diabetes, with its abnormal blood-chemistry and general functional dysbalance, to secure the easy, complete, and regular removal of intestinal residues. It is one of the oldest of observations that any degree of constipation aggravates the diabetic condition.

Mild salines, which do not irritate the intestinal lining, acting solely through their power of retaining fluid according to osmotic law, stimulating peristalsis in a natural way by mere bulk, are usually the laxatives to be preferred; but owing to the nausea and discomfort produced by the mineral sulphates, and the even greater harm in diabetes caused by the disguising of these salts with sugar and flavouring agents, most saline preparations are rightly regarded with disfavour.

It has been found, however, that in Eno's "Fruit Salt" is available to diabetic patients an effective saline laxative, entirely free from the unpleasant mineral salts, and with no trace of sugar or added flavour. A teaspoonful of Eno in a glass of water is a refreshing effervescent drink with an agreeable taste, due solely to its own composition and texture.

"The Doctor's Emergency Reminder."

The Proprietors of Eno's "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest addition to their series of "Medical Reminders"—with or without a bottle of their preparation (Handy or Household size as required). "The Doctor's Emergency Reminder" summarises briefly a few points in connection with the treatment of poisoning and various other emergency cases. It is bound in black morocco limp to conform to the style of the previous publications in this series.

J. C. ENO LTD., 160, PICCADILLY, LONDON, W.1

Throughout the span

of allotted years — from infancy with restricted diet, through manhood with irregularity of habits, to old age with failing muscular strength and intestinal atony, constipation besets "all types and conditions of men."

The remedy lies not in the doubtful results of harsh cathartics, but in helping the colon back to normal activity.

AGAROL
BRAND
COMPOUND

The original agar-agar emulsion

is dependable, mild, non-irritating to the organs. It lubricates the intestinal tract, softens the impacted fæces, and reactivates the peristaltic force and action.

A liberal quantity of Agarol Brand Compound for trial sent without cost or obligation to physicians.

Agarol Brand Compound is the *original* Mineral Oil—Agar-Agar Emulsion (with Phenolphthalein) and has these advantages:
Perfect emulsification; stability; pleasant taste without artificial flavouring; free from sugar, alkalies and alcohol; no oil leakage; no griping or pain; no nausea; not habit forming.

NEW EDITIONS of BEST SELLERS

5 EDITIONS IN 5 YEARS

BEAUMONT & DODDS

FIFTH EDITION. 48 Illustrations. 12s. 6d., postage 6d.

RECENT ADVANCES IN MEDICINE

By G. E. BEAUMONT, D.M., F.R.C.P., Physician, Middlesex Hospital; and E. C. DODDS, M.V.O., M.D., M.R.C.P., Professor of Biochemistry in the University of London.

"There is no other single volume which so adequately correlates the progress of modern medicine in the distinct, yet mutually dependent fields of clinical medicine, laboratory work and therapeutics. . . . Additions to nearly every chapter bring the book completely up to date, thus making it invaluable to practitioners who, while anxious to keep up with modern medical thought, have little time in which to peruse the enormous amount of medical literature which is published."—PRACTITIONER.

FIFTH EDITION. 1,054 pages. ONE GUINEA. Postage 1s.

STARLING'S PHYSIOLOGY

Edited and Revised by C. LOVATT EVANS, D.Sc., F.R.C.P., F.R.S., Jodrell Professor of Physiology in University College, London. With chapters on the Central Nervous System and Sense Organs revised by H. HARTRIDGE, M.A., M.D., Sc.D., F.R.S., Professor of Physiology, St. Bartholomew's Medical College.

FIFTH EDITION. 280 Illustrations. 25s., postage 9d.

A TEXT-BOOK OF MATERIA MEDICA

By HENRY G. GREENISH, D. ès Sc., F.I.C., F.L.S., Professor of Pharmaceutics to the Pharmaceutical Society of Great Britain.

38 Illustrations. 18s., postage 9d.

THE CHEMICAL ANALYSIS OF FOODS

A Practical Treatise on the Examination of Foodstuffs and the Detection of Adulterants.

By H. E. COX, M.Sc., Ph.D., F.I.C., Public Analyst, Metropolitan Borough of Hampstead.

"The whole book is thoroughly practical, and describes in an intelligible manner methods of food analysis which can be trusted to give reliable results."—THE LANCET.

NINTH EDITION. 8 Plates, 273 Illustrations. 28s., postage 9d.

PRACTICAL PHYSIOLOGICAL CHEMISTRY

By P. B. HAWK, M.S., Ph.D., President of the Food Research Labs. Inc., New York City; and O. BERGEIM, M.S., Ph.D., Asst. Prof. of Physiological Chemistry, University of Illinois, College of Medicine, Chicago.

By J. A. CROWTHER, Sc.D., F.Inst.P., Professor of Physics, University College, Reading.

MOLECULAR PHYSICS & THE ELECTRICAL THEORY OF MATTER

FOURTH EDITION. 7s. 6d., postage 4d.

THE PRINCIPLES OF RADIOGRAPHY

With 55 Illustrations. 7s. 6d., postage 4d.

By W. M. CROFTON, M.D., Lecturer in Special Pathology, Univ. Coll., Dublin.

THERAPEUTIC IMMUNISATION

THEORY AND PRACTICE.

7s. 6d., postage 5d.

PULMONARY TUBERCULOSIS

ITS DIAGNOSIS, PREVENTION, AND TREATMENT.

6s., postage 5d.

MEDICAL BACTERIOLOGY AND HELMINTHOLOGY

By L. E. H. WHITBY, C.V.O., M.C., M.B., Assistant Pathologist, Middlesex Hospital. 10s. 6d., postage 6d.

121 Illustrations, many in Colour. 15s., postage 9d.

SURGICAL ANATOMY

By GRANT MASSIE, M.S.Lond., F.R.C.S., Demonstrator of Anatomy, Guy's Hospital.

NINETEENTH EDITION. 10s. 6d., postage 5d.

HALE-WHITE'S MATERIA MEDICA:

PHARMACY, PHARMACOLOGY, and THERAPEUTICS.

SECOND REVISED EDITION. 273 Illustrations. 25s., postage 9d.

GWATHMEY'S ANÆSTHESIA

WITH COLLABORATORS ON SPECIAL SUBJECTS

SECOND EDITION. 21 Illustrations. 18s., postage 9d.

A SYNOPSIS OF HYGIENE

By W. WILSON JAMESON, M.D., M.O.H., Borough of Hornsey; and F. T. MARCHANT, M.R.San.I., Senior Assistant in Department of Hygiene, University College.

London: 40, Gloucester Place, Portman Square, W.1

MACMILLAN

SIR CLIFFORD ALLBUTT

A Memoir

By SIR HUMPHRY ROLLESTON, Bart., G.C.V.O., M.D.,
Regius Professor of Physic in the University of Cambridge. With Portraits. 15s. net.

Morning Post.—"Sir Humphry Rolleston's Memoir is an admirable tribute to this admirable man's memory; it is a triumph of completeness and conciseness, with many a flash of the literary distinction appropriate to its subject."

The PREVENTION of HUMAN TUBERCULOSIS of BOVINE ORIGIN

By WILLIAM G. SAVAGE, M.D.(Lond.), D.P.H., County Medical Officer of Health, Somerset; Author of "Milk and the Public Health." 10s. 6d. net.

British Medical Journal.—"It should have a wider circulation than most technical books; in fact, it can be read with interest by anyone, for apart from the medical profession it will be welcomed by veterinarians, agriculturists, and local government workers . . . Space forbids more than this brief mention of only a few of the interesting sections of a most valuable book."

THE GLANDS REGULATING PERSONALITY

A Study of the Glands of Internal Secretion in Relation to the Types of Human Nature.

An important book on Sociology.

HEREDITY IN MAN

By

H. RUGGLES GATES, Ph.D., LL.D., F.L.S., F.R.A.I.

Author of *Heredity and Eugenics*, etc. 24s. net.

Heredity in Man is the outcome of the author's earlier book, Heredity and Eugenics. The chapters on physical inheritance have been retained and greatly extended in the present work, which is in all essentials a new book.

Dealing extensively with the inheritance of normal conditions as well as the abnormal in man, it is the fullest account of human heredity in the English language.

The author has made important contributions to genetic anthropology, and the chapter on racial crossing summarises the striking recent developments in this field.

The book may be regarded as an important contribution to medical, anthropological, genetical, and eugenical literature, which will be indispensable to those interested in any aspect of human heredity.

A TEXT-BOOK OF

PULMONARY TUBERCULOSIS

By

R. C. WINGFIELD, B.A., M.B.(Oxon.), F.R.C.P.

Demy 8vo. Illustrated. 31s. 6d. net.

Considerable attention—both official and general—is being devoted to the subject of pulmonary tuberculosis. National tuberculosis services have been inaugurated, from which the practitioner may obtain the assistance and advice of men specially trained in observation of the disease, and who, by intensive study, may ultimately find some solution to the problem. These services are rapidly increasing in efficiency; but unfortunately there are some less satisfactory than others, in which case (quoting from the pages of the "British Medical Journal"): "the practitioner will be well advised to turn to such a book as that of Dr. Wingfield, from which he will obtain a sane estimate of what can, and what cannot, be done for a tuberculous patient."

"This book is clearly written and full of information which will be appreciated not only by the student but also by tuberculosis officers and others interested in consumption. . . . A text-book on tuberculosis was wanted. This one can be thoroughly recommended to all interested in tuberculosis, not only as a text-book but also as a work of reference."—THE LANCET, July 13th.

ALLEN & HANBURYS, LTD. :: :: Lombard Street, London, E.C.3.

WHOOPING COUGH

The best practice in the treatment of whooping cough recognizes the importance of keeping the patient out of doors as much as possible. The food should be easily digestible, nourishing, and given a little at frequent intervals.

There are no specifics for this disease. In very young children drugs are administered with difficulty and are of uncertain effect.

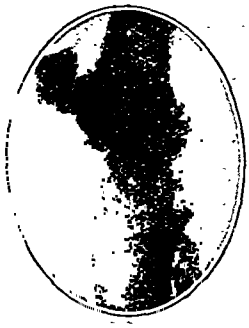
Vaporized Cresolene at night will be found a simple and effective means of preventing the paroxysms at that time, thus tending to preserve the strength of the patient, avoid complications, and hasten convalescence.

'IODOLYSIN'

Trade Mark.

A Powerful Fibrolytic Agent

Strikingly Successful in Chronic Arthropathies



Radiograph of Knee-joint in Rheumatoid Arthritis

A fibrolytic agent which gives really satisfactory results in a large percentage of cases must appeal to the general practitioner who has constantly to deal with difficult and intractable cases of chronic rheumatism and allied conditions. This can be justly claimed for 'Iodolysin' which has a striking effect in Rheumatoid Arthritis; and it is also employed with advantage for the removal of all forms of pathological fibrous tissue.

'Iodolysin' is a chemical combination of Iodine and Thiosinamin with these special advantages:

Ready Solubility in water. Well tolerated. Absence of local reaction on injection

'Iodolysin' is supplied in ampoules for hypodermic injection; in capsules for oral administration, or as an ointment or paint for local application.

Radiograph of Hip-joint in Rheumatoid Arthritis

Made by

CARR'S of Carlisle

Intestinal Disinfection

ARTERIO-SCLEROSIS

IT is an old adage that a man is "as old as his arteries," meaning that degenerative changes in the arteries are largely responsible for senility.

The modern view is that arterio-sclerosis is produced by increased blood-pressure, and that increased blood-pressure results from the absorption of "pressor" substances developed by putrefactive bacteria in the intestine.

(Prof. A. Robin, among his suggestions for the treatment of arterio-sclerosis, emphasises in the first place the need to remove the alimentary toxic factors which are causative of arterial hyper-tension.—"Therapeutique Usella du Praticien," p. 344.)

To retard the activity of the putrefactive bacteria, Metchnikoff introduced the soured milk treatment; but how much better it is to use an antiseptic substance. The ordinary so-called intestinal antiseptics, such as Salol, possess little real disinfectant power, and more potent germicides, such as Phenol, are absorbed, and, in sufficient dose, are toxic.

The active principle of Kerol, besides being a very potent germicide, is not absorbed, and is therefore non-toxic. The rational treatment of arterio-sclerosis would, therefore, include adequate intestinal disinfection by means of the keratin-coated Kerol Capsules.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

Colloidal Hydroxide of Aluminium

THE increasing prevalence of gastric ulcer and hyperchlorhydria has produced an advance in the treatment of these diseases.

"Alocol" (Colloidal Hydroxide of Aluminium) provides an antacid medicament far superior to subnitrate of bismuth, bicarbonate of soda and other alkalis. These merely afford a certain degree of ease, without bringing about a permanent relief of the condition.

"Alocol" absorbs the excess of hydrochloric acid without interfering with the normal antiputrefactive function of the gastric juice or harmfully affecting the processes of nutrition.

"Alocol" has been subject to extensive clinical trial, and literature giving full particulars of the results will be gladly sent to medical men on request.

For Acute or Chronic Cases of Hyperacidosis

For Gastric Duodenal or Pyloric Ulcers

A. WANDER, Ltd., Manufacturing Chemists

M.232.

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.

May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.

It cannot harm the most delicate constitution and is at all times a safe and effective aperient.

DINNEFORD and Co. LTD.

NASAL CREAMS

DUNCAN'S Nasal Creams are put out in Elastic Gelatine Capsules suitable for applying a medicament to the higher nasal passages. The following different kinds of creams are offered:

Dimol

IMPROVED

Plombières Lavage

For greater convenience in the preparation of this lavage, the Dimol Powder is now supplied in packet form ready for use. Each packet contains sufficient powder for one pint.

Extract from Report recently received from one of the largest Hydros in England.

"I am very pleased to report that the thirty cases treated with the Dimol Lavage have shown a marked improvement in their general condition; as examples I quote the three following cases:—

"A gentleman who had suffered for many years from chronic diarrhoea received six Dimol Colonic Lavages combined with Faradism over the colon. Result: Complete cure.

"Youth, 18 years of age, who had previously had rheumatic fever. Present diagnosis: General debility, slightly anaemic, chronic intestinal toxaemia. Treatment: C. Arc. 12 Plombières with 80 grains Dimol. Result: Marked improvement. Gained 14 lbs. in one month.

"Lady (Oxyuris Vermicularis). Treatment: Five Plombières with 80 grains Dimol. Result: Completely cured.

"I think that your new innovation of making up 80-grain dosages an ideal one, as it effects a considerable saving of time.

"Numbers of my patients have now become firm adherents to the Dimol Pulverettes as a result of the considerable benefit they have derived from the Dimol Lavage."

Price, in cartons of Six—4/- Professional Discount 20%

Special Terms to Hospitals and other Institutions.

Copies of Capt. Ainslie Walker's brochure giving full particulars of the improved Plombières Lavage will be sent on application to:—

The Standard of Purity of

INSULIN "A.B."

TRADE A B MARK **Brand**

The ideal Insulin should be so pure that its use is entirely free from any untoward effect. This is the aim of the makers of Insulin "A.B.", who have adopted their own stringently high standard of purity and have always maintained it. Reductions in their prices have never involved the slightest sacrifice of quality.

Insulin "A.B." is so pure—and therefore so free from reaction-producing proteins—that the number of clinical units per milligram of substance approaches the maximum possible, i.e., the equivalent of crystalline Insulin.

The world-wide supremacy of Insulin "A.B." is due to this unequivocal purity no less than to its well-known potency and stability under all conditions.

REGETHERM POULTICE
(Cataplasma Kaolini. B.P.C.)
CLEAN & CONVENIENT IN USE

More certain in its action than the old-fashioned poultice.

The healing action of Regetherm Antiphlogistic Poultice is governed by its ability to prolong and maintain an even degree of heat over a lengthy period. Moreover, the ingredients are so balanced that this action does *not* set up any counter-irritation, but allays pain, ensures an even circulation through the congested areas, and thus induces natural and pain-free rest.

The Medical Profession will appreciate the fact that the action of Regetherm Poultice is much superior to that of fomentations or linseed poultices, and can be relied upon as an efficient aid in the treatment of all types of inflammation—whether local and superficial, or of deep-seated origin.

HEWLETT'S
ORIGINAL PREPARATIONS.

HORMONIGEN
(HEWLETT'S)

Hormonigen Tablets (Hewlett's) contain the hormones of the thyroid, pituitary, ovary, and testes.

Useful in Neurasthenia and all asthenic conditions, obesity, chronic cardiac cases, aplasias of the [illegible] and in anæmia. In Ai[illegible], and at the Meno-pa[illegible] Hormonigen is particularly effective, and even in chlorosis.

If there is high blood pressure, Hormonigen Sine Pituitary is indicated.

PRICE: HORMONIGEN, OR HORMONIGEN SINE PITUITARY,

3/3 PER 100; 30/- PER 1,000.

UNG. IODERMIOL

An ointment of IODERMIOL that contains about 5 per cent. of Iodine, and is, therefore, stronger than the B.P. Ointment, whilst it does not harden or discolour the skin.

It has been found most useful for Enlarged Glands, Rheumatic and Gouty Affections, Lumbago, Sciatica, Swollen and Stiff Joints, Skin Diseases, Ringworm, etc. Ung. Iodermiol has also been used in cases of burns and scalds, and in the treatment of Chronic Lymphadenitis, Simple Bronchocele, and Atrophic Rhinitis, and in Purulent Ulcerative Otitis.

PRICE 6/- PER LB.

UNGUENTUM IODERMIOL et METHYL SALICYL. (HEWLETT'S)

Useful in the treatment of Enlarged Joints, Synovitis, Rheumatoid Affections, etc.

PRICE 7/6 PER LB.

LIN. BETULÆ CO.
(HEWLETT'S)

Therapeutically equivalent to several times its weight of Sodium Salicylate without causing headache, tinnitus, etc. Has proved most useful in the external treatment of pure Rheumatism, Sciatica, Lumbago, etc. The external dose is about one drachm rubbed over the affected parts.

In 5, 10, 22, 40, and 90-oz Bottles.

PRICE 10/6 PER LB.

VERONIGEN
(Formerly known as MIST. VERONAL CO.)
(HEWLETT'S)

A liquid Preparation of this prompt and reliable HYPNOTIC has long been desired as a useful means of procuring sleep. When given in reasonable doses it is claimed that it does not produce any toxic symptoms whatever, and in ordinary cases of insomnia one fluid drachm of Veronigen (Hewlett's) is quite sufficient dose for an adult.

Dose for Adults.—One fluid drachm diluted, about one hour before going to bed.

For Nervous Sleeplessness in Children.—10 to 20 minims diluted.

VERONIGEN, 10/6 PER LB.

MIST. PRUNI VIRG. CONC.
(HEWLETT'S)

A valuable stimulant and expectorant cough mixture, containing Carbonate of Ammonium, Ipecacuanha, Senega, Squill, and Syrup of Wild Cherry Bark. Quite free from Morphine, Opium, or poisons, so can be safely administered to children.

Dose: 1 to 2 drachms diluted.

In 22, 40, and 90-oz. Bottles only.

PRICE 3/3 PER LB.

MIST. TUSSI RUB. CONC.
(HEWLETT'S)

A favourite and economical cough mixture, containing Hydrobromic Acid, Chlorodyne, Dilute Hydrocyanic Acid, etc. Most successful in allaying post-influenza coughs that are so persistent. One or two ounces diluted with water to make eight ounces forms one of the most effective and elegant mixtures that can be made, and certainly the least expensive.

In 22-oz., 40-oz., 4½-lb., and 8-lb. Bottles only.

PRICE 2/9 PER LB.

The Safe Milk for Baby-

—is sterilized Evaporated

Libby's Milk is the milk that builds sound, strong bodies, and gives better health for infants and children. It is the milk that is pure, never varying in quality, with not a particle of the food substances of ordinary milk taken away. Libby's is "homogenized" milk, which means that it is milk with all the fat globules scientifically broken up and evenly distributed—milk in a form that is admitted to be the most easy to digest of all. That is why Libby's Milk, fed to infants according to our Feeding Tables, not only means good health, but happier and healthier babies.

£1000 *will be paid*

to any Hospital or other public charity if it can be proved that the claims made for Libby's Milk are not in accordance with scientific facts.

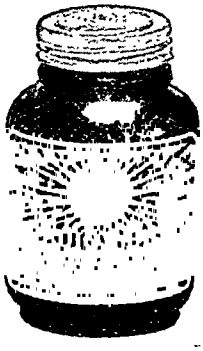
RADIO-MALT

and

'the importance of the preventive aspects of medicine'

THE trend of modern medicine is towards prevention rather than treatment; it is suggested, in effect, that the treatment of disease is of secondary importance in comparison with the prevention of it, and that the principal function of the family physician should be that of an adviser on methods of maintaining health. When acting in this capacity as adviser, the physician appreciates the importance of diet and habit; he is gratified that there is available for inclusion in his armamentarium a scientific product of the nature of Radio-Malt which possesses in a remarkable degree the power to raise the resistance of the human body against septic and infective organisms, and is therefore of unique value in combating their attack.

A small daily dose of about a teaspoonful taken during the Autumn will have the effect of building up a reserve of power to withstand the onslaught of infection when colds, influenza and other epidemics of the winter months are rife.



In periods of stress such as in pregnancy, during the physiological changes of puberty and the menopause, and in fact at all times when there is abnormal strain upon the system there is need of just such sustenance as is available through the administration of this unique product.

Vit. Pr./82

NATURALLY RICH IN VITAMIN 'D'

"SMILER"

Intensive investigations into the use of synthetic vitamin D preparations have not yet been completed, but the possibility of hypervitaminosis has already been definitely established, and the dangers of excessive prescribing have been demonstrated.

Cow & Gate Milk Food

"Cow's Milk made safe and suitable for Baby."

In the irradiation of milk so many factors are involved besides those of the production of vitamin D that up to the present authorities have agreed that its use is not permissible except under carefully controlled conditions. Vitamins D occurs in sufficient quantities in fresh milk from cows fed on the rich pastures of the West of England ; and such milk, when dried by the improved COW & GATE roller process, suffers no appreciable loss of vitamin D. The result is a clean basic milk containing *natural* vitamin D in adequate proportions for the maintenance of perfect and healthy growth. Physicians recommending this product avoid the risk of unknown factors and are prescribing a pure and unadulterated preparation of the highest repute, which has been used with outstanding success for over a quarter of a century.

The makers will gladly supply samples for Clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

ANCIENT CHINESE BAS-RELIEF ON WHICH APPEARS A FABLE CONCERNING *ELIXIR VITAE*.—In China, the quest for *elixir vitae* undoubtedly originated in a real desire to find a remedial drug to cure disease and prolong life. Although their concoctions were mostly valueless, the Chinese physicians did real pioneer work towards this end, for, in addition to giving the elixir, they prescribed deep breathing and various calisthenic exercises conducive to health. Lao-tzŭ himself, in the 6th century B.C., prescribed, in addition to "the wonderful elixir *produced by the pestle of jade*," the following exercise for obtaining longevity: "Let one sit straight with his mouth shut and not allow a single thought to arise in his mind. Let him forget everything and keep his spirit with settled purpose . . . . Let him draw long breaths and gradually emit them, without a break, now seeming to breathe and now not. In this way any excitement of the mind will naturally disappear, the water from the kidneys will rise up, the saliva will be produced in the mouth, and the real efficaciousness becomes attached to the body. It is thus that one acquires the way of prolonging life." In Chinese fable, the hare and toad, here depicted as inhabitants of the moon, were linked up with the search for *elixir vitae*.

VITAMINS A, B & D
HAVE ALWAYS BEEN IN CADBURY'S MILK CHOCOLATE.

Fresh milk only is used in Cadbury's Milk Chocolate, which is made by a distinctive process incorporating the fresh milk direct with the chocolate.

By this process, the important Vitamins A, B and D, natural to fresh milk, are retained.

Owing to its concentrated form (there are 1½ glasses of milk in every ½-lb. cake) the chocolate is appreciably richer in Vitamin D than milk itself. Further, it contains the whole of the bone-forming calcium and phosphates present in the milk. All the essentials of an anti-rachitic food are contained in Cadbury's Milk Chocolate.

The dietetic value of milk has always been recognised by the medical profession—a convenient and concentrated form is Cadbury's Milk Chocolate.

This chocolate is sold in 2d. Bars, 6d. Packets, and 1/- ½-lb Blocks.

Remarks ON THE PATHOGENESIS AND TREATMENT OF ASTHMA.*

BY

ARTHUR F. HURST, M.D., F.R.C.P.,

SENIOR PHYSICIAN TO GUY'S HOSPITAL.

THIS is the sixth occasion on which asthma has been discussed at the Annual Meetings of the British Medical Association since 1900. At the meeting in 1911 nothing was said which was not known to Hyde Salter when he wrote his admirable book on asthma fifty years before. At the meeting in 1921 the recent introduction of skin tests was regarded as holding out prospects of curing asthma with a frequency hitherto unapproached, a prospect which was already seen to be doomed to disappointment at the discussion in 1925. Though no new discovery of importance has been made in the four years which have elapsed since then, the large amount of work which has been done in the investigation of asthma in all parts of the world has, I think, led to a better understanding of the problem with which we are faced, and treatment founded on a thorough study of each asthmatic individual from every point of view is now likely to be followed by improvement, though unfortunately not often by cure.

The chemical constitution of the body fluids is not exactly the same in all healthy individuals, but shows slight variations from the average normal. I believe that these slight variations, though compatible with perfect health, form the basis of the congenital and often inherited constitutional tendency to develop certain diseases.

The balance between the vagal and the sympathetic constituents of that part of the respiratory centre in the medulla which, together with the associated peripheral ganglia, controls the activity of the muscular coat and mucous glands of the bronchi, is perfectly adjusted in normal individuals. I believe that the asthma diathesis—the congenital and often inherited constitutional abnormality which is the one essential factor in the pathogenesis of asthma—is caused by a slight deviation from the average blood chemistry, which results in the vagal constituent of the bronchial nervous system being the predominant partner. In such individuals certain chemical, reflex, and psychical stimuli, which have no effect on normal individuals, give rise to spasm of the bronchial muscles and hypersecretion of the bronchial mucous glands, together with congestion of the bronchi, which is the natural accompaniment of their excessive functional activity.

Some indication of the nature of the primary biochemical factors which predispose to asthma has recently been discovered by Dr. Oriel (*Guy's Hospital Reports*, lxxix, October, 1929), whose investigations at Guy's Hospital have demonstrated that even in the intervals between attacks the blood of asthmatics generally shows certain divergences from the average normal.

A further biochemical factor depends upon the varying activities of the internally secreting organs. The effect of fatigue, as shown by the increased tendency to asthma towards the end of each day, each week, and each period of work without holiday, is best explained as the result of exhaustion of the suprarenal glands, whose deficient secretion helps the vagal constituent of the bronchial nervous system to gain the upper hand over the sympathetic constituent, the activity of which requires an adequate supply of adrenaline. In accordance with this theory the blood pressure of asthmatics is generally low, and Oriel has found that many of them have well-marked hypoglycaemia. The increased tendency to attacks just before or during menstruation in many female asthmatics must also depend upon some alteration in the normal balance of the internal secretions.

In recent years so much attention has been directed to the question of hypersensitiveness to proteins and other chemical substances in asthma that there has been a tendency to regard this as the one essential factor. The truth is, however, that an individual who is hypersensitive to one or more proteins only suffers from asthma if he has the constitutional tendency, the nature of which I have just described, and there is no doubt that many asthmatics are not hypersensitive at all, their attacks being caused by reflex and occasionally psychical stimuli. It is none the less of the greatest importance to give every asthmatic an exhaustive cross-examination with the object of discovering whether some or all of his attacks are due to his being hypersensitive to the proteins of one or more articles of food, an animal emanation, a pollen, house-dust, orris-root face powder, or the toxins of some organism, which is present in his body owing to infection of the bronchi themselves, the tonsils, nasal sinuses, teeth, or even the appendix or gall-bladder. I have used the skin tests in a very large number of cases since my attention was first drawn to them during a visit to America in 1919, but in spite of trying a great variety of American and English preparations I have regretfully come to the conclusion that they are of no practical value, except in the case of food proteins in children and of pollens at all ages. Harding has come to the same conclusion from his investigations at the Guy's Hospital Asthma Clinic.

The nose is the most important reflex source of asthma. Brodie and Dixon showed that stimulation of an area on the septum in animals produces bronchial spasm. In individuals with the asthma constitution irritation of the corresponding area gives rise to a similar reflex. When a man with a narrow airway lies down at night, the passive congestion of the cavernous tissue of his turbinals may be sufficient to bring them into contact with the asthmogenic area on the nasal septum. The narrow airway may be congenital or result from a deflected septum or from chronic infection which leads to permanent congestion of the mucous membrane and the development of polypi. A distended stomach and a distended rectum may both produce reflex attacks of asthma quite independently of any form of alimentary toxaemia, an evacuation of the stomach or rectum producing immediate relief long before a change could take place in the blood from diminished absorption of poisons.

The most common psychological factor in asthma is expectation. An individual who has been accustomed to get attacks of asthma in certain places or under certain conditions is exceedingly likely to continue to do so when the original chemical or reflex cause has ceased to be operative. This is a result of auto-suggestion, but it must be remembered that no amount of suggestion can produce anything more than tachypnoea without any trace of over-activity of the bronchi in anybody who has not the asthma diathesis.

TREATMENT.

In discussing the treatment of asthma we have to consider the underlying constitutional abnormality, the chemical, reflex, and psychological factors which can initiate an attack, the attack itself, and the secondary changes in the lungs which result from repeated attacks. It is clear that the only true cure of asthma would be to abolish the diathesis by bringing the biochemical constitution of the body fluids to the normal level. Removal of exciting factors leads to diminution of the frequency of attacks, and complete success in this direction may lead to an apparent cure. But the condition is not really cured, as the diathesis remains, and at any time the individual may become sensitized to another protein—as, for example, after an attack of influenza or other infection involving the nose, throat, or bronchi—or a new peripheral source of irritation which leads reflexly to attacks may arise, or some psychological disturbance may develop which results in a relapse. Moreover, the effects of desensitization are only temporary, and avoidance of exciting causes, such as feathers, cats, or pollens, even for long periods, does not diminish the tendency to asthma on re-exposure. I used to say that the only cure of asthma was not to have it, by which I meant that one might hope that the bronchial nervous system might cease to be abnormally irritable as a result of disuse if it were never called into activity. But this is unfortunately not always true, at any rate in adults, as I have now seen numerous patients who have relapsed after thinking themselves cured for periods varying between one and twenty-five years. Lastly, treatment of the paroxysm

* Made in opening a discussion in the Section of Medicine at the Annual Meeting of the British Medical Association, Manchester, 1929.

is of the greatest importance, as, if successful, it may make it possible for a man to continue in full activity instead of becoming a hopeless invalid.

Among the innumerable forms of treatment which have been advocated two appear to attack the diathesis; these alone, if successful, might be regarded as genuine "cures." The first is by means of diet, a treatment which has been very successfully applied, especially in children, by Dr. Adam and Dr. Cameron. The second is by residence at a height between about 4,000 and 6,000 ft. Asthma is almost unknown among the natives of the Engadine, Davos, Villars, and similar centres in Switzerland, and at least 90 per cent. of asthmatics lose all, or nearly all, their symptoms within a very short period of their arrival in these places. Unfortunately, the effect is only temporary if the stay is a short one, the asthma returning, often within a few hours, on reaching the plains. But residence for one year, or preferably several years, in the Alps almost invariably leads to a permanent cure in children, in spite of complete failure of every known form of treatment at home. Storm van Leeuwen attributed the effect of the Alps to freedom from dust. I am convinced that this is erroneous, as there is no obvious difference between the hotels at a height of 4,000 ft. and those 2,000 ft. lower, and yet a man who is severely asthmatic in the latter is often quite well and can take vigorous exercise within twenty-four hours of moving to the former. Moreover, no house could be fuller of "allergens" of every kind than the hermetically sealed chalets of the Alpine peasants during the winter, although asthma is unknown among them. It is also a common experience among asthmatics that conditions which invariably lead to asthma when they are at home are innocuous in the mountains; it seems, in fact, that nothing could produce an attack when the 4,000-ft. level has been reached. It is clear that the effect is due to altitude, a conclusion which has been confirmed by the experience of asthmatic members of the Air Force, who find that they can always find relief by flying sufficiently high. It is unknown why altitude should have this remarkable effect, but I expect it will be found that the lowered oxygen tension leads to biochemical changes in the blood, which result in diminution in the irritability of the bronchial nervous system. The further lowering of oxygen tension when a still greater height is reached has the reverse effect, though each individual appears to have an optimum level. This accounts for the reappearance of attacks on reaching greater heights in the Alps and the frequency of asthma in such places as Johannesburg.

It is, I think, possible to look forward to the time when sufficient is known about the biochemical changes which constitute the asthmatic diathesis to make it possible to imitate the effect of high altitudes by well-defined changes in the diet, aided, perhaps, by drugs which can correct deviations from the normal reaction of the body fluids and make good any deficiencies in their mineral or other constituents. I should mention here the success obtained by Dr. Oriel, especially in children, by adding glucose to the diet, together in most cases with the regular administration of alkalis.

Some of the many chemical stimulants of the irritable bronchial centre can be avoided by a change in habits, diet, or environment. Others can sometimes be rendered innocuous by desensitization.

With regard to reflex exciting causes, it is necessary to emphasize the importance of avoiding distension of the stomach and the rectum. In the case of the nose there are three distinct factors which require attention. The first and most common is chronic infection of the sinuses, especially the ethmoids, with secondary development of polypi; this must be dealt with by the cure of the infection, which can generally be effected by vaccination and packing with silver preparations without more radical operations than the removal of polypi. The second factor is obstruction of the nasal passages; it is essential to overcome this, as few asthmatics can be permanently relieved if they remain mouth-breathers. Lastly, the asthmogenic area on the nasal septum should be either destroyed by cauterization or rendered inoperative by so correcting the other factors present that the turbinates no longer come into contact with it, even when distension of their cavernous tissue occurs as a result of gravity on going to bed. Chronic bronchitis, which also acts both as a reflex cause and as a focus of infection with organisms to the toxins of which the individual is sensitized, should be treated by autogenous vaccination, small doses of iodide, and climate.

The psychological factor requires consideration in the treatment of every case of asthma. At least 75 per cent. of patients become either completely free or almost free from symptoms directly they enter a hospital or clinic. This is doubtless often in part due to the fact that they have got away from the allergens present in their homes, which were responsible for some of their attacks; it is often partly and sometimes entirely due to the expectation that they are going to derive benefit from the treatment they are about to receive. It is essential to bear this in mind in estimating the effect of any treatment. If, for example, they are at once put into a dust-free chamber or are given some new drug, it is natural that they will ascribe the inevitable improvement to the specific treatment, whereas in all probability an equal degree of improvement would have occurred without any active treatment at all. It is always wise to instil a spirit of optimism into asthmatics, and to make them realize that improvement may at any time occur and that conditions which formerly gave rise to asthma may cease to do so. In this way alone can the influence of expectation in the production of attacks be overcome. A wise physician will also rarely fail to find some way in which unobtrusive psychotherapy benefits his patient.

In the treatment of the asthmatic paroxysm the preponderating activity of the vagal nerve supply to the bronchi can be overcome by means of drugs, such as atropine, which paralyse the vagus, or by adrenaline, which stimulates the broncho-dilator fibres of the sympathetic. The inhalation of fumes from powders containing stramonium or belladonna, which was formerly the universal method of treatment, had the grave disadvantage of causing chronic bronchitis by irritating the bronchial mucous membrane. This treatment should now never be used, as the opposite method of restoring the balance by means of adrenaline has no such disadvantage and is also more promptly and more constantly effective. The patient should be taught to inject the adrenaline himself, as if he does this at the first sign that an attack is developing it will be aborted, and a single minim will often be sufficient, though five or more would have been required if he had had to wait for a doctor or a nurse to give the injection at the height of the attack. This small dose gives rise to none of the unpleasant symptoms often caused by larger doses, and as it does not even raise the blood pressure there is no danger of damaging the arteries. Its use has in many cases the further justification of making good a deficiency in the secretion of adrenaline, just as thyroid preparations do good in myxoedema. The treatment also reproduces the way in which relief may on rare occasions occur under natural conditions. If an individual during a severe attack of asthma comes under the influence of sudden fear or anger, the two emotions which Cannon showed stimulate the secretion of adrenaline, the attack immediately ceases, the patient having had an "autogenous dose" of adrenaline. We may hope that the time will come when asthma will be curable, but until that consummation has been attained the proper use of adrenaline deprives asthma of most of its terrors and makes it possible for every asthmatic to live a life of moderate activity. Before its introduction many asthmatics rarely slept for more than three or four hours a night, and the morning found them exhausted by the long-continued fight for breath. Now it is unnecessary for any asthmatic to resort to hypnotics, as even if he has three or four attacks in the night the prompt injection of the right dose of adrenaline will each time send him to sleep within a few minutes.

The rare condition of status asthmaticus, in which severe asthma continues uninterruptedly for days or weeks and may end in fatal exhaustion, can always be arrested by the method of continuous adrenaline injection, which I introduced a few years ago, and which we have since found is equally effective in the treatment of anaphylactic shock. The needle is kept constantly in position, and after an initial injection of a dose which is known to cause no

unpleasant symptoms, such as two or three minims, one or more minims are injected every fifteen, thirty, or sixty seconds, according to the patient's reaction, the rate being varied until it is found how frequently the injection can be made without any unpleasant symptoms arising. The injections are continued, if necessary, for even half an hour or more; relief always follows and generally manifests itself by the patient falling into a deep sleep, which is often the first he has had for several days.

During the last few years a vegetable product, ephedrine, has been much employed as a substitute for adrenaline. Its chemical constitution is very similar, and it has the advantages of acting when taken by the mouth, whereas adrenaline is destroyed in the stomach, and of producing a much more prolonged effect. But it acts less rapidly and only controls minor degrees of bronchial spasm, being quite useless in the treatment of severe paroxysms. It is specially useful in overcoming the slight dyspnœa and wheeziness from which many asthmatics suffer in the intervals between attacks, and it is a very useful prophylactic when taken before going for a walk or doing anything else which is known by past experience to be likely to bring on a mild attack. Sometimes, when taken in the evening, it prevents an attack in the night, but occasionally it has the disadvantage of causing insomnia.

As the increased positive intrathoracic pressure during forced expiration increases the bronchial obstruction in an attack of asthma, whereas the negative pressure during inspiration diminishes it, the dyspnœa of asthma is characterized by being mainly expiratory. The result is that from the onset of the attack the lungs are in a state of full expansion, which after a time tends to persist in the intervals between attacks, especially if, as is often the case, the spasm does not completely disappear. The distended condition of the lungs is not true emphysema, as the latter depends upon permanent structural changes in the tissues of the lungs, which make it impossible for them to be restored to their normal size. On the other hand, the distended lungs of the asthmatic remain capable of contracting unless secondary emphysema has occurred as a result of associated chronic bronchitis. The distended lungs are in a condition of great disadvantage, as there is no means of increasing their capacity when exertion calls for more oxygen. It is therefore of the greatest importance to teach every asthmatic to perform regular expiratory exercises, by means of which his barrel-shaped chest and shrugged shoulders become much less obvious, and in the case of children often disappear completely. Corresponding with this his capacity for taking exercise is enormously increased, as deep inspiration now becomes as easy as deep expiration. Ordinary breathing exercises are quite useless, if not actually harmful. Each exercise should begin with expiration, and an effort is made by active and passive movements to restore the thorax to a normal position of rest, after which diaphragmatic breathing with the mouth closed and the body fully relaxed should be taught.

Sir John Floyer, the author of the first monograph on asthma in any language, "panted on to ninety," in the expressive words of his fellow townsman, Dr. Johnson. There is, I think, reason to hope that before long our knowledge of the fundamental cause of asthma and of its treatment will have advanced so far that restoration to good health, and not merely the attainment of a miserable old age, will be the usual outlook for the asthmatic.

THE CEREBRO-SPINAL FLUID IN INTRACRANIAL INFLAMMATION.*

BY

J. G. GREENFIELD, M.D., F.R.C.P.,

PATHOLOGIST, NATIONAL HOSPITAL, QUEEN SQUARE, FOR DISEASES OF THE NERVOUS SYSTEM.

THE subject chosen for this discussion offers considerable difficulties. In no part of the body is it more necessary to understand all the stages and processes of inflammation, and in no place is this more difficult than in relation to the meninges overlying the cranial air sinuses. The subject has been made still more difficult by an old-fashioned nomenclature, which reflects theories of pathogenesis bearing little relation to modern physiology and pathology. The terms "meningitis sympathica" and "meningitis serosa," for example, are not only meaningless in themselves, but are interpreted by every author in a different way. Attempts have therefore been made to discard these terms, and new terms, such as "protective meningitis," have been introduced. This term seems to be little less meaningless than the older ones, as all forms of inflammation are regarded as "protective" by some pathologists, and in the case of meningitis the success of the protective mechanism is usually very uncertain. I prefer, therefore, to think of these forms of meningitis as either generalized or more or less localized.

We are now considering an infective process which resembles inflammation elsewhere in the body so long as it remains localized, but which is likely to prove fatal if it spreads a short distance from its starting point. Thus, if it penetrates the dura mater and reaches the brain, or spreads along the subarachnoid space to the larger cisterns, or causes inflammation of the walls of the dural venous sinuses, it at once becomes dangerous to life.

The first question that arises, therefore, is, What are the chances that the infection will remain localized? In this connexion we have to remember the density of the dura mater and the remarkable power it has of preventing the spread of infection so long as there is free external drainage. Of the infections that reach the dura mater very few penetrate it. We must also remember that the subarachnoid space over a large part of the base of the brain is very narrow. Keith considers that the beautiful convolutional pattern which is seen on the floor of the skull indicates that the brain rests firmly on the bone with no fluid cushion between. The bony ridges which run along the lines of the sulci must reduce the subarachnoid space there to an almost negligible size. There is therefore a good chance that an infective leptomeningitis over the outer parts of the anterior and middle cranial fossæ may be limited by meningeal adhesions. With regard to the posterior cranial fossa it is probable that the subarachnoid space over the lateral lobes of the cerebellum is also very restricted, except in the immediate neighbourhood of the pons. On the whole, therefore, an infection from the middle ear is more likely to pass across the subarachnoid space to the brain and cause cerebral abscess than to cause widespread meningitis. On the other hand, an infection which runs inwards to the tip of the petrous bone, or which arises in one of the more centrally placed air sinuses, is much more likely to cause generalized meningitis, owing to the proximity of the large cisterns.

In my experience it is in the cases of more or less localized meningitis that the chief difficulties of diagnosis arise. When we are presented with the fluid from a typical case of septic meningitis containing numerous organisms in films and on culture it needs none of the refinements of the clinical laboratory to establish the diagnosis. When, on the other hand, no organisms are visible and cultures remain sterile the difficulties begin.

The examination of such sterile fluids requires special care and a well-devised routine, as the quantity of fluid is limited. We must first determine whether the fluid is normal or not in cell count and protein percentage. If it is normal in these respects, especially if the pressure is also normal, the prognosis is usually good. But even slight abnormalities, such as a small admixture of polymorphonuclear cells in a "high normal" lymphocyte count, or a rise in the protein with little or no cell increase, may be danger signals. In some cases the fluid is quite normal but the pressure is increased, a condition more often found in the "meningism" of general diseases in childhood than in local inflammatory conditions of the skull and dura mater. In general diseases the symptoms of meningitis usually disappear quickly after the first puncture; in inflammatory conditions the increase of pressure may remain for some little time and only disappear after several punctures. It is probable that in the first case we are

* Read in opening a discussion in the Section of Oto-Rhino-Laryngology at the Annual Meeting of the British Medical Association, Manchester, 1929.

dealing with an increased secretion of fluid owing to some metabolic or vascular abnormality, whereas the second class of case is more probably due to some temporary disturbance in absorption of cerebro-spinal fluid.

Of abnormalities in the fluid the most common is an increase in the number of cells, of which a moderate or high percentage are polymorphonuclear associated with a moderate increase in albumin and globulin. The fluid may appear clear or very slightly turbid (a condition to which the term "serous meningitis" has been given), or more definitely purulent. The chief objection to the term "serous meningitis" is that it is impossible to draw any line between "serous" and "purulent" types of meningitis. They run into one another by insensible gradations. The condition should be looked at simply as evidence of the presence of a septic focus in the neighbourhood. This meaning is to some extent conveyed by the name "meningitis sympathica." The focus may be (1) dural or extradural, (2) in the brain as a cerebral abscess, or (3) in a localized pocket in the subarachnoid space. Toxins, and possibly a few bacteria, are continually escaping from this focus and causing a reaction in the subarachnoid space in the neighbourhood. The presence of a high proportion of polymorphonuclear cells is evidence of a sharp fight between the bacteria and the resisting powers of the pia arachnoid. A gradually increasing percentage of mononuclears shows that the defence forces are prevailing. It is sometimes possible to tell by a comparison of the cell count with the excess of protein whether the infection is limited to the meninges or whether there is a cerebral abscess. For whereas in dural infection the protein will always be proportional to the increase of cells, in the case of brain abscess there is usually a further addition of protein to the fluid from the oedematous brain tissue which surrounds the abscess. Therefore in cases of abscess the cerebro-spinal fluid generally contains proportionately more protein than cells. This lack of balance is easily made out in subacute and chronic cases when the cell count is low. Taking two recent cases as examples, I found in one 110 mg. protein with four lymphocytes, and in the other 80 mg. protein with ten lymphocytes.

With purulent fluids it is more difficult to form a just estimate of the balance between cells and protein, but in some of my cases the fluid, when cleared of its purulent turbidity by centrifugalizing, was found to contain more than 1/2 per cent. protein, a percentage which is practically never found in simple meningitis. This "protein-cell dissociation" is not constant, but when it occurs may be a useful diagnostic point.

It is often said that the prognosis becomes worse as the fluid becomes more turbid. This may be true for successive punctures on one case, but it is by no means true for an isolated specimen of cerebro-spinal fluid. I have seen so many patients with heavily purulent sterile fluids recover that I am inclined to be hopeful about such cases. On the other hand, when the fluid is less purulent we may be seeing the onset of a widespread meningitis. The presence of many cells without bacteria is evidence that the patient is putting up a strong fight, just as a fluid which is turbid from bacteria but contains very few cells shows that the patient's resistance has been overwhelmed. In cases of cerebral abscess it is probable that the cell count varies inversely with the thickness of the wall of the abscess cavity, and therefore spread of the infection and rupture into the ventricle are more probable when the fluid is full of polymorphonuclears than when there is a low cell count consisting chiefly of mononuclear cells. But in any case of abscess the risk of death from increase of intracranial pressure is so great that an operation is always necessary. It would seem, therefore, that the answer to the question whether operation is indicated or not depends to some extent on whether the diagnosis of cerebral abscess can be made.

Considerable attention has been paid in these cases to an examination of the *glucose* in the cerebro-spinal fluid. The modern view is that the reduction which is so frequently found in the glucose is chiefly due to the liberation of glycolytic ferments by degenerating cells. So long as the cells are living the glucose remains normal, or may even be increased. The presence of dead pus cells, on the other hand, is shown by a fall in the glucose. The estimation of the amount of glucose in an isolated specimen of cerebro-spinal fluid has therefore very little more value than the cell count as a prognostic sign, but the return of a low glucose percentage towards normal figures in successive punctures is definitely of good omen.

As regards the *chlorides*, it is generally accepted that they are reduced in generalized meningitis and normal in localized meningitis and abscess. It used to be considered that the fall in generalized meningitis was due to the increase in meningeal permeability which is known to occur in that condition. Recent work by Fremont-Smith and by Linder and Carmichael, however, has shown that the reduction in chlorides is fully accounted for by a parallel drop in the blood chlorides. This drop occurs in many general infective conditions, especially in septicaemia, and may be taken as evidence that the patient's powers of resistance are lowered. From a prognostic standpoint, therefore, a low chloride percentage in the cerebro-spinal fluid still has the same unfavourable significance as we have always attributed to it. Our new knowledge of the rationale of the fall in the chlorides helps us, however, to understand the reduction of the chlorides which is often found in otherwise normal cerebro-spinal fluids, as well as the anomalous cases of generalized meningitis in which the chlorides remain normal.

Cracked Cribriform Plate.

With reference to the pathology of cerebro-spinal rhinorrhoea I wish to say something about the cases in which the cribriform plate is cracked without any rhinorrhoea occurring. The cases of this kind that I have seen have almost all been due, curiously enough, to motor bicycle accidents. Sometimes the rider and sometimes the pedestrian is the victim. The history in several of my cases was that after recovery from concussion there was a period of weeks or months during which the patient was moderately well. Then he caught a cold and at once presented symptoms of meningitis. In the first case of this kind which I saw, the patient had two such meningitic attacks at intervals of several months and succumbed to the third with a pneumococcal meningitis. In another case, a child, who was knocked down by a motor, had no symptoms for several months except slight fits, for which he was attending the National Hospital, Queen Square. Then about Christmas time, following a cold and cough, he was brought into hospital unconscious, and died within twenty-four hours of fulminating streptococcal meningitis. At the necropsy I found that the left cribriform plate and the overlying dura mater had been completely absorbed, and their place filled by unhealthy granulation tissue. We have had other cases in which the presence of cerebro-spinal rhinorrhoea or pneumocephalus made the diagnosis easier. But in the two cases I have mentioned the possibility of a crack of the cribriform plate with subsequent absorption of the bone was not thought of. It seems to me that diagnosis should be possible before meningitis sets in, and that the masterly inactivity which is so often the only treatment should be replaced by some form of prophylaxis; otherwise the patient's life is in continual danger.

It must be emphasized that the outlook in cases which follow concussion is much graver than in cases where the cribriform plate is cracked during operations on the nose. The difference lies in the fact that there is always an increase in the intracranial pressure for some days, weeks, or even months after concussion. This increase of pressure acting on a weakened place in the bony case, such as a cracked cribriform plate, will usually prevent proper healing, whether membranous or bony, from occurring there, and no proper barrier will be formed against the invasion of micro-organisms from the mucous membrane of the upper air passages. In operative cases, on the other hand, healing takes place without any hindrance, and the patient is probably no worse off than before, except, possibly, for a loss of the sense of smell on that side.

SURGICAL TENDENCIES IN MODERN MIDWIFERY.

BY

ELIS ESSEN-MÖLLER, M.D.,

PROFESSOR OF OBSTETRICS AND GYNAECOLOGY AT THE UNIVERSITY OF LUND, SWEDEN.

THE art and science of midwifery is in our days developing in a manner which seems to be as important as it is interesting. By physiological research one tries to investigate the biology of pregnancy *in normal and pathological conditions*. By *x* rays, pelvic measurements, examinations of the urine, and so on, one tries in time to detect various anomalies and apply a prophylactic treatment of them which may lessen the risks for the mother and her child. *Finally*, one aims at the same purpose by substituting with increasing frequency surgical intervention for the older obstetrical methods, in the hope of serving the interests of both. It is about this last-named feature of modern obstetrics that I want to say a few words.

The difference between past obstetrical methods and those at present employed is very striking; this is apparent if we consider for a moment the risks of a difficult labour in old times. If the foetus could not pass through a narrow brim one at first had nothing else to do than patiently wait for the accommodation of the foetal head. If that hope failed, there was no other resource than a version, an accouchement forcé, a Caesarean section, or an embryotomy, perhaps on a living child. In cases of placenta praevia, the only resource was the tamponade until version could be performed; in eclampsia venesection and chloroform were the only means to avoid new fits. Prophylactic treatment was *wellnigh unheard of*; from the natural forces one expected the utmost possible, which *in many cases* was the same as the impossible.

On the other hand, we should do a great injustice if we denied the merits of the old midwifery. The careful observation of the labour increased the knowledge of the mechanism of labour. The diagnostic ability of the obstetricians, their power of prognosis and appreciation of intervening anomalies advanced midwifery practice to a remarkable degree, and their patience—which is called the first virtue of the obstetrician—was tried to an extent which in our days is rather rare. Smellies, Boers, and Baudelocques are bred only in such times, not in ours.

But their great merits stand out against a dark background. I only mention infections, lesions of the pelvis or the soft parts of the mother, asphyxia, cranial infractions, and so on, which, if they did not kill the mother or child, perhaps made them invalids for the rest of their lives. The number of such cases cannot be appreciated in statistics, but is easily understood.

The great advancement did not come at once, but as isolated flashlights. Among those who should be remembered with the deepest gratitude I cannot refrain from mentioning such British names as Macaulay, Smellie, Denman, and Lister.

The most important advancement from our point of view dates from the end of the last century, and is combined with the revival of the classical Caesarean section and the invention of the vaginal one. By the former we got the means of avoiding a great deal of the dangers of a narrow pelvis; by the latter we learnt to open the uterus and empty it at any time during the pregnancy or labour without risking the incalculable accidents of accouchement forcé. This epoch is not so far away but that we all remember it. We all of us remember, too, the hopes it aroused. No one who lived through that time can wonder at it, nor at the exaggerations that necessarily followed upon it.

Personally, if I may be permitted to say so, I was educated in the principles of the old obstetrical school. The circumstances then were such that at a very young age I was entrusted with the directorship of the University Hospital for Women, and that exactly at the time I have alluded to. It was thus quite natural that a young man, who on many occasions had the opportunity of witnessing the insufficiency of the older methods, should begin to try if the new ways could give better results than the older ones. Thus it came about that I became a convinced partisan of the new surgical aspect of obstetrical therapy, and have done what I could to propagate it in Sweden.

But now there appears to me to be a tendency to go so far that even to a convinced partisan it seems difficult to keep pace. Let me state in as few words as possible my outlook upon the question, which seems to me important for the near future of obstetrics. To begin with the credit side of the surgical interventions, nobody denies that it is now possible to open and empty the uterus at any time during pregnancy or labour. What that signifies in eclampsia, in placenta praevia, in accidental haemorrhage, or in acute cases in which the life of the mother is threatened I need not insist upon. Neither can it be denied that the operations in question are so far technically perfect that the primary risk is very small.

It is far from my intention to proclaim them harmless; no surgical intervention is that. But considering the lesions which unfortunately sometimes occur, it is only fair to compare them with the quite incalculable and sometimes irreparable ones that so often follow upon accouchement forcé or a difficult labour in cases of narrow pelvis. Furthermore, there is no doubt that, as the surgical procedures are performed only in well-equipped hospitals, at the right time, by skilful and experienced hands, they are combined with lesser risks of infection and primary lesions. I do not think it possible to deny this. In that case it stands to reason that the surgical aspect of obstetrics has earned results for mother and child which could not have been obtained in any other way. As far as I can judge, nobody nowadays wishes for a return to the midwifery of older times.

But the medal has a reverse. The risk or value of an operation should not be appreciated only after the primary results, such as infection, embolism, and so on. The secondary ones are just as important. I will only mention two of them. One is the risk of thinning or rupturing of the scar after Caesarean section, the frequency of which in Britain has been thoroughly investigated by Herbert Spencer, Eardley Holland, and others. The other is of a kind which has not been seriously dealt with as yet—namely, the fear of the mother after Caesarean section that she may become pregnant again, and the significance such a state of mind may possibly have for the population. The effort by Caesarean section to get a living child may thus be in some degree neutralized by the mother who wishes to avoid further intervention of the same kind, and the operation thus has consequences which perhaps one has not thought of earlier.

Of course, I think it is fair to admit that the extension of the indications is in itself the natural consequence of the remarkable primary results, but the question arises whether, in these days, intervention has not sometimes been carried too far. It is difficult to discuss indications. A man who applies forceps in 3 per cent. of his cases probably considers a frequency of 6 per cent. or 10 per cent. exaggerated. Those who perform version only on certain fixed indications will certainly be considered behind the times by Dr. Potter of Buffalo, who seems to consider version to be a normal procedure in ordinary labours. And I know of a clinic where the frequency of interventions amounts to 90 per cent., against 10 per cent. of spontaneous labours.

I will give two special examples of what I consider unnecessary and therefore regrettable exaggerations.

Dr. Hirsch of Berlin is very keen on the extension of surgical methods in obstetrics, especially abdominal Caesarean section, to all abnormal labours, and he claims that this will bring about a new orientation in midwifery. He argues that the puerperal mortality has been stationary for a rather long time, and that mothers and children die who would have been saved if the mothers

* Read in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association, Manchester, 1929.

had been sent to a hospital without previous vaginal examination and operated upon in time.

To my understanding the efforts of Dr. Hirsch are creditable in so far that the early removal of complicated cases to hospitals and the omitting of unnecessary vaginal examinations would certainly bring about a decreasing puerperal morbidity and mortality. But to me it seems exaggerated to go so far as Hirsch wants to do. The new orientation that he so strongly advocates and wishes to introduce is already partly realized, and the surgical tendencies in obstetrics are nothing new. I myself have performed Caesarean section in 20 out of 200 patients with placenta praevia. I believe that no experienced obstetrician would hesitate about Caesarean section if he was really convinced that this operation would confer a better prognosis without increasing the risks for mother or child. Neither do I believe in the necessity or possibility of transferring all cases to hospitals, as Hirsch insists upon. The majority of labours go well by means of natural forces alone, and there is indeed no branch of medicine that in ordinary circumstances can be performed so efficiently and safely in the patient's home as obstetrics.

Furthermore, Dr. Hirsch's handling of the statistical figures does not quite appeal to me. Generally speaking, it is difficult to get reliable statistics on this special point. I particularly wish to draw attention to the very thorough and excellent investigation of the Caesarean sections performed in Germany in 1928 which has been recently published by Winter. It really does not point in the same direction as Hirsch, but quite the contrary. For the present I am therefore of the opinion that Hirsch overrates the possibilities of Caesarean section, while he at the same time underrates what can be done by simpler methods without surgical intervention.

Another example of misjudging the Caesarean section has been given recently in Sweden, when a colleague put the question: "Why does not one perform that operation more frequently in order to shorten the labour and alleviate the pains of the mother?" I need not here go into a detailed criticism of such a proposal, which seems to indicate that the desire for more speed, which is such a characteristic feature of our days, threatens to extend into the domain of obstetrics.

I should venture to go farther and say that these and other efforts to extend surgical intervention in obstetrics are indicative of a too superficial understanding of childbirth. Labour is decidedly a physiological process, the most difficult and strenuous that the human organism is able to perform. Who knows the deeper effects of such an enormous effort on the body of the mother herself? The coming into life of new individuals is associated not only with risks, but also with means of safety which may be considered as wellnigh perfect. When trying to follow and understand them we are reminded of the words of our great Linnaeus: "Deum omnipotentem a tergo transeuntem vidi." And we ought to remember, too, that nothing great and dear in life is attained without struggle and suffering. If we try to reach the goal by easy byways, we may perhaps find that we have lost more than we have gained.

No; surgical intervention is not intended to shorten a physiological process, nor merely to alleviate it. It is permissible only after thorough consideration of the pros and cons. It requires of the obstetrician a patient observation and infallible recognition of commencing complications, the power of choosing the way of the greatest safety, and, not least, a sufficient surgical training. These qualities can be demonstrated by choosing a surgical procedure which is considered advisable or necessary, but they can also be just as well shown by abstaining from interfering in a physiological process if the interference is unnecessary or risky.

THE TREATMENT OF HYPERPIESIA.*

BY

A. H. DOUTHWAITE, M.D., F.R.C.P.,

ASSISTANT PHYSICIAN, GUY'S HOSPITAL.

BEFORE dealing with the details of treatment of this prevalent disease I propose bringing to your notice a medley of symptoms, any one or more of which may be indicative of its existence. In the first place, we find that cases of hyperpiesia may be divided into three types:

1. *Menopausal*, in which the common vasomotor disturbances are only too apt to divert attention from the possibility of associated hyperpiesis. The subjects present increasing obesity and other signs suggestive of hypothyroidism—for example, loss of hair, waxy colour of the skin, and subnormal temperature.

2. *Plethoric*, preponderating in males of 40 years or more, who are fat with florid facies and short, thick neck. Often this type has for years taken freely of food and alcohol, but sparingly of exercise; this, however, is by no means always the case. The majority suffer but little from symptoms of the disease, and form the greater part of those dying suddenly and unexpectedly.

3. *Sallow*, found chiefly in females, the disease commencing generally at an earlier age than that of the first two types. The picture presented is that of the patient with viscoptosis and intestinal toxaemia. The skin is muddy in appearance, dark rings are present beneath the eyes, the tongue is thickly furred, and constipation is the rule. These people are thin, "wiry," energetic workers, seldom given to alimentary indiscretions, but over-conscientious in the performance of their tasks. This is the type which actually suffers so greatly from the disease which afflicts it, and which responds the least readily to treatment. I lay stress on its description, because the lean patient is prone to pass through our hands incorrectly diagnosed, the possibility of a raised blood pressure never having been considered.

We must recognize, also, that hyperpiesia is by no means a disease whose onset is peculiar to middle life. Genuine cases are met with in young adults and in adolescence—a fact which those of you whose work includes the routine examination of school children will confirm.

Lastly, in this connexion, should be mentioned the type of patient whose blood pressure reading may lead to the diagnosis of hyperpiesia, yet in whom the hyperpiesis is transitory and the result of apprehension only. It is a matter of common knowledge that the first estimation of blood pressure in a strange patient is unreliable, but in some cases nervousness may produce truly surprising results. Thus a male patient whom I saw recently had blood pressures of 220/130. Suspecting this as a case of "fictitious" hyperpiesia, I took a series of readings during the next half-hour. They were 180/125, 160/120, 145/100. Actually he was suffering from peripheral neuritis, but he thought that the pains in his arm were due to angina pectoris, a disease of which a near relative had died. Whether this form represents a potential hyperpiesia, a hyperpietic in embryo, is, I think, a point worthy of consideration.

SYMPTOMS.

The variety of symptoms of hyperpiesia is one of the characteristics of the disease. It is therefore of importance that they should be briefly considered, because many of them do not immediately suggest to the physician the presence of cardio-vascular disorder. I have arranged these roughly in order of descending frequency as noted in one hundred consecutive cases.

Shortness of breath on exertion and headache vie for pride of place. I have previously shown[2] that the headache is of two types: one is the true dull ache, not uncommonly present even with the decline of high pressure; the other is an acute lancinating pain, the head feeling as if it were about to burst. This pain is always associated with, and presumably due to, a definite exacerbation of the hyperpiesis. In contradistinction to the true ache, it responds promptly to measures which lower the blood pressure. On the other hand, one is struck by the patients presenting

*An address delivered before the Dover Division of the British Medical Association, May 11th, 1929.

systolic pressures of 200 mm. of mercury or more who to the day of their death never complain of headache.

Palpitation, tachycardia, and inability to lie on the left side are again of great frequency. Of this triad palpitation needs the greatest emphasis, because it is a symptom found in association with many functional nervous disorders, and the possibility of organic disease is apt to be overlooked.

Giddiness, which is usually dizziness, as opposed to true vertigo, may be a transient symptom produced by stooping or coughing, or it may be most persistent, and is then always associated with well-marked general arterio-sclerosis. Sudden attacks of definite vertigo are decidedly less common, and, if associated with vomiting, are to be regarded as of serious portent. Careful examination will usually reveal evidence of a central nervous lesion, presumably a small haemorrhage, such as unilateral facial weakness and an extensor plantar response.

Noises in the ear are of two kinds. The one is in the nature of a low-pitched pulsation, and responds well to treatment; the other, tinnitus, consists of various whistling, hissing, high-pitched sounds, and is present only if arterio-sclerosis is recognizable. Reduction of the hyperpiesis has no beneficial effect.

Anginal pain, though not uncommon, rarely gives rise to the intense paroxysms of anguish which characterize the disease, as generally recognized. Nevertheless I believe that we should accept the symptoms of substernal tension, or pressure, brought on by hurry, and relieved by rest, as definitely indicative of the presence of those factors necessary to produce eventually the fully developed syndrome. By insisting on a reduction of mental and physical activity we can thus postpone for many years the onset of a fatal seizure.

Mental symptoms are of diverse character, and on the whole not common. In the first place, our patient may complain of nervousness only, this symptom being most common in the sallow female type. She is harassed by trivial annoyances, and by fears based on no good cause, by palpitation, sleeplessness, and so on. She is only too apt to be placed in the category of functional nervous disorder, yet recovers from her symptoms with abatement of hyperpiesis.

The robust hyperpietics in the first few years of the disease exhibit unusual mental vigour; but with the onset of arterio-sclerosis, drowsiness in the middle of the day may develop into a genuine cause for complaint. Failing memory, particularly for recent events, is a feature common to all classes, and advances in relation to structural changes of the cerebral vessels.

The most startling, but rare, change in mentality which I have met with has been a sudden onset of acute mania, the condition being invariably associated with a fall of blood pressure of considerable degree—for example, from 220 to 130 mm. of mercury. The psychosis continues until the hyperpiesis re-establishes itself. In the cases I have observed there has been no demonstrable physical change to be held accountable for the lowering of the tension.

Haemorrhages, retinal and nasal, are of common occurrence and give rise to great anxiety. The former frequently leave permanent impairment of vision, but improvement in sight may take place over six months. Epistaxis is particularly alarming, owing to its profuseness and difficulty of control. Apart from this, it may be regarded as a blessing, possibly averting a cerebral catastrophe. I have seen instances of melaena, haematemesis, and uterine haemorrhage for which no other cause than the existent hyperpiesis could be discovered. The possibility of this as the cause of sudden haemorrhage should, therefore, be borne in mind.

Pains in the limbs, and pain or a clutching sensation in the throat, are referable to the stretching of the local arteries by the excessive pressure of their contents. The latter symptom is particularly liable to be mistaken for one of functional origin.

I have not been impressed by symptoms referable to the urinary tract. In the later stages of the disease, when arterio-sclerosis is a pronounced feature, frequency of micturition is common. Apart from these circumstances, however, it is a rare symptom.

Signs.

Physical examination may reveal little more than a raised systolic pressure with a varying degree of exaltation of the diastolic reading. Before hypertrophy of the left ventricle is recognizable the most constant sign is the accentuation of the sound produced by the closure of the aortic cusps, together with a raising of its pitch. The last feature represents, I believe, atheromatous changes in the vessel with thickening of the valve segments. When absent the probability of "fictitious hyperpiesia" should be borne in mind.

The peripheral vessels show changes after variable periods, sooner in the thin and wiry individual than in the plethoric sufferer. When the radial artery appears to be normal to the examining fingers, the brachial is often grossly abnormal. The sensation imparted is that of a leathery toughness, rather than the hard pipe-stem condition common in senility. The retinae should be examined in every case, for here may be found arterial disease long before it is apparent elsewhere.

The most constant change which I have found in the blood is that of a raised cholesterol content,[2] often above 200 mg. per 100 c.cm. Whether this is of any etiological significance remains to be seen. In the meantime, it is of interest to note that there is an appreciable increase of the substance in atheromatous vessels;[1] furthermore, I have notes of eighteen of this series suffering also from gall-stones, a number too high to be explained on mere coincidence. My impression is that the highest cholesterol figures are obtainable from those hyperpietics exhibiting rapidly developing arterio-sclerosis. In a young woman exhibiting this feature to a remarkable degree a cholesteatoma was also removed from the skull. The erythrocyte count and blood urea are normal for many years. In the later stages a mild secondary anaemia and slight rise of urea may occur.

The urine in the majority of my cases was absolutely normal on repeated examinations. The appearance of a trace of albumin and a few hyaline casts is, of course, to be expected with advance of years and arterial disease.

The alimentary tract, as has been noted, gives rise to complaint in the lean individual on account of obstinate constipation. The tongue is commonly furred and visceroptosis is present. On the other hand, the plethoric individual has a clean tongue, powerful peristalsis, and high acid content of the gastric juice.

Causes of Hyperpiesia.

In considering the possible causes of hyperpiesia we must accept a disturbance of the endocrine system as the probable basis of our menopausal type. The association of menopause, obesity, loss of hair, sluggish mental processes, and rising blood pressure is too obtrusive to be overlooked, and this type of case responds well to treatment with thyroid extract. That overactivity of the suprarenal medulla may be a factor in the production of hyperpiesis has been postulated, and it is of interest to note the increase of blood cholesterol which has been found in association with hyperpiesia and a hypertrophied adrenal cortex.

On the other hand, the young, lean, constipated patient with furred tongue and foul breath lends support to the theory that protein decomposition products are absorbed from the intestine and, failing to be destroyed in the liver, exert a pressor influence on the systemic arterioles. True there is no conclusive evidence in support of this, but some of us may lean towards this explanation in view of the suggestive clinical type.

The robust patient presents peculiar difficulties. Often he has been exceptionally athletic in youth, but has later assumed a sedentary existence without at the same time reducing his intake of food. May it not be, therefore, that his powers of elimination are overtaxed, and that the basic fault is the same as in the previous group?

We must frankly admit that all these theories may be utterly wrong, yet as working hypotheses, and on the results of treatment, I feel they deserve more consideration than the view favouring the presence of a circulating pressor substance derived from diseased kidneys. To me

it is inconceivable that renal disease could produce hyperpiesis of many years' standing in the presence of a constantly normal urine.

TREATMENT.

Exercise should be restricted only in so far as is dictated by the patient's symptoms and signs. I mean by this that it is quite useless to send a patient to bed simply because he has a high blood pressure. Immobility may lower it 10 to 20 mm. of mercury, seldom more, frequently less or not at all. Avoidance of hurry, especially after meals, of excitement, excessive exertion, and exposure to cold is naturally essential, particularly in the presence of anginal symptoms. These restrictions, however, interfere but little with the essential side of the patient's life, and are therefore all the more likely to be observed.

Diet.—Here, again, I believe that the prevalent custom of excluding all meat from the dietary is pointless. If we accept the theory of intestinal toxaemia, it may perhaps be reasonable to reduce the protein intake, but a restriction to meat thrice weekly is ample. On the other hand, eggs, brain, liver, and fat should be largely excluded in an attempt to lower the cholesterol in the circulation. In the obese glutton the diet should be a rigid one, and composed of fresh fruit, fish, and vegetables. Alcohol, with the exception of light wines, should be forbidden.

Purgatives.—The daily use of saline cathartics is obnoxious and useless, possibly harmful in fact, by increasing the blood viscosity. Cases of obstinate constipation respond to a vegetarian diet in conjunction with abdominal massage and the exhibition of a non-irritating laxative such as sulphur, psyllium seeds, paraffin, or bemax.

Drugs.—We can dispose of the majority of those in common use with rapidity. Nitrites are valueless except in emergencies—in angina, for example—on account of the transitory nature of their action. Iodides I have never found of help in cases unassociated with syphilis. At one time it was believed that they lowered the viscosity of the blood and thus aided its flow. In order to attain this effect the dosage must be enormous, while the digestive disturbances they produce are most objectionable. Bromides are of value in allaying restlessness and producing sleep in the nervous type of patient. Indirectly the blood pressure may thus be lowered. These salts are also of use in overcoming tinnitus. Thyroid extract is seldom helpful except in the obese menopausal patient. Here it can be highly efficacious, and should be prescribed in doses rising from 1/2 grain thrice daily up to ten times this amount, provided that symptoms of intoxication do not arise.

Veratrum viride. We now come to the consideration of a drug with definite effect in reduction of hyperpiesis, the actual preparation used having been veratrone. A few years ago I employed this substance on a series of cases[5] and found that it reduced the blood pressure when administered by mouth or intravenously. In the former case the effect was variable even on the same patient, and it should be remembered that individual susceptibilities also present great differences. Briefly the effect of intramuscular injection of 1 c.cm. is to lower the blood pressure from, say, 185/110 to 105/63 in half an hour, and the original level is regained in the course of one to two hours after administration. Such a big drop should, of course, be avoided, as it is attended by nausea, retching, and even collapse. On the other hand, 1/2 c.cm. resulted in a fall from 190/123 to 120/70 in half an hour in one patient, and from 200/130 to 150/105 in another. Given by the mouth 1/2 to 1 c.cm. will in many cases lower the systolic pressure from 20 to 30 mm. of mercury and keep it about this level for two hours. The drug may be regarded as of undoubted value, but it must be used with great caution in view of the possibility of idiosyncrasy. In very susceptible patients it may produce an alarming fall of blood pressure even if administered per os.

Acetylcholine, an acetyl ester of choline, stimulates the parasympathetic system and antagonizes adrenaline. Its effect in lowering arterial tension is produced by dilatation of the arterioles, the capillaries being unaffected. The actual preparation which I have used is "acécoline," which consists of acetylcholine hydrochloride stabilized with glucose. The resulting powder must be dissolved immediately before use, and the solution injected intramuscularly. Oral administration is useless, intravenous injection is extremely dangerous. As a precautionary measure, therefore, the piston of the syringe should be withdrawn before injection to ensure against an accidental delivery of the drug into the blood stream. The initial dose should be 0.05 gram, raised subsequently to 0.1 gram daily. The effect of the former dose is to produce a steady fall of systolic pressure, commencing within half an hour of administration, reaching its lowest level in three to four hours, and passing off gradually with a return to the former height in seven to nine hours after the injection; 0.1 gram produces its greatest effect in six to eight hours, and the previous pressure is often not reached until fifteen hours after administration. As examples may be cited the following results on the same patient, a female of 59 years, with hyperpiesia, normal urine, and moderate arteriosclerosis.

Time.	Blood Pressure (Systolic).
11.0 a.m.	160 mm.
Acécoline 0.05 gram injected.	
12.30 p.m.	160 mm.
2.30 ,, ...	115 ,,
3.30 ,, ...	120 ,,
8.40 ,, ...	150 ,,
10.0 ,, ...	165 ,,
10.30 a.m.	175 mm.
Acécoline 0.1 gram injected.	
11.30 a.m.	165 mm.
4.15 p.m.	130 ,,
5.15 ,, ...	124 ,,
6.15 ,, ...	142 ,,
7.30 ,, ...	150 ,,
8.30 ,, ...	160 ,,
9.15 ,, ...	170 ,,

Although I have as yet used the drug in only a small number of cases, yet I feel justified in drawing your attention to its action in the hope of gaining your co-operation in further investigations. It is clear that acetylcholine has a much more prolonged action than that of the drugs previously discussed, and it has the advantage of not producing sudden falls of pressure, which have caused the objectionable symptoms following the use of veratrone. On the other hand, the fact that oral administration is valueless is a decided point against its general adoption. We have yet to find whether a course of injections will produce a lasting effect on the hyperpiesis. There are already indications that it will do so, and some authors[5] advise doses of 0.1 or even 0.2 gram night and morning for fifteen consecutive days each month for three months.

You may object that by reducing the blood pressure we are merely dealing with a feature of the disease, rather than the cause. This is perfectly true; nevertheless it is justified in view of the fact that by so doing the heart and blood vessels are relieved of excessive stresses, at any rate for several hours in the day. The summation of such respites, taken over a year, must represent an enormous saving of effort to the heart muscle.

In advanced cases of hyperpiesia with extensive vascular disease a lowering of blood pressure of any extent is, of course, contraindicated, for it might result in depriving the narrowed cerebral vessels of their necessary blood supply. Judgement must therefore be used in choosing suitable subjects for this treatment.

Diathermy is of value in the treatment of hyperpiesia; in some a course produces a substantial reduction of blood pressure, and the improvement may persist for three or four months. On the whole, the results are disappointing.

Venesection is an old remedy, still unsurpassed in value by more modern measures. It is particularly appropriate for the obese, florid type of man who is unable, or unwilling, to carry out any dietary restrictions or consecutive treatment. The sallow patient often responds, however, equally well to free bleeding. Headache, giddiness, and roaring in the ears vanish as if by magic, and the improvement is maintained for two or three months. The imme-

diate result of venesection on the blood-pressure is often very slight, and quite out of proportion to the alleviation of suffering; but during the following two or three days progressive fall may be observed. After this it may remain steady at its new level, or may rise again to its former height, yet the urgent symptoms do not return for many weeks.

Eliminative Treatment.

This is essentially a line of attack on the sallow, toxic type. For twelve consecutive days the patient is given 1/10 grain of pilocarpine hypodermically, followed by a hot wet pack, which is again followed by massage. Twice weekly during the course colon lavage is carried out. The diet during this time should consist of fresh fruit, vegetables, fish, brown bread, and butter. Before meals two tumblerfuls of Vichy water are to be taken. The beneficial effect on the patient's appearance, symptoms, and signs is very evident. The course may be repeated every two months, and can be carried out, if necessary, at home. Annual treatment at Harrogate is peculiarly suitable for this class of patient.

You will observe, then, that no hard-and-fast rule can be set for the treatment of hyperpiesia, but each case must be considered in relation to type, symptoms, and physical signs. Given such discrimination, we can undoubtedly bring great relief to our patients, and, I believe, prolong life for the majority.

PROGNOSIS.

Finally, the difficult problem of prognosis. You will agree that one great lesson learned in general practice is, particularly in cases of hyperpiesia, to give a cheerful outlook. Seven years ago I saw a lady with a blood pressure of 220/150, retinal and small cerebral haemorrhage, dyspnoea, obesity, and oedema of the ankles. Both types of haemorrhage were repeated within a month. It was thought unlikely that she would live two years, yet she is still highly active, never suffers from headache, and presents a systolic pressure of 220 mm. or over.

As a general rule, a high diastolic pressure renders the prognosis more gloomy, as do also clear signs of cardiac or arterial disease. The menopausal type presents the most hopeful form, the lean patient the least favourable, on account of the earlier onset and rapid arterial degeneration. It is true, also, that the occurrence of retinal or cerebral lesions more often than not heralds the approach of a fatal termination.

Patients over 60 years of age survive in the most astounding manner in spite of the presence of some, or all, of the signs usually indicating a bad prognosis. The outstanding example in my practice was that of a man of 70, known to have had a high blood pressure for at least thirty years. On three occasions he developed auricular fibrillation, which was overcome by quinidine, and once he developed diarrhoea, incontinence of urine, pyrexia, petechial haemorrhages, and a streptococcus was recovered from his blood. And yet he lives!

The anginal pains to which I have referred are not of the same gloomy significance when a high blood pressure is present as when it is absent. They disappear with reduction of hyperpiesis.

In all cases we should, of course, warn the relatives of the possibility of cardiac failure, coronary thrombosis, fatal angina, and cerebral haemorrhage. The patient, on the other hand, should be encouraged, as far as is consistent with ensuring his attention to our therapeutic efforts.

BLINDNESS IN OLD AGE.*

BY

J. JAMESON EVANS, M.D., C.M., F.R.C.S.,

HONORARY OPHTHALMIC SURGEON, ROYAL INSTITUTE FOR THE BLIND, BIRMINGHAM; HONORARY SURGEON, BIRMINGHAM AND MIDLAND EYE HOSPITAL.

UNDER the provisions of the Blind Persons Act of 1920 it was enacted that "Every blind person who has attained the age of fifty shall be entitled to receive and to continue to receive such pension as, under the Old Age Pensions Acts, 1908 to 1919, he would be entitled to receive if he had attained the age of seventy," and the provisions of those Acts, including the provisions as to expenses, shall apply in all respects to such person as if for the first statutory condition there were substituted a condition that the person must have attained the age of fifty, and be so blind as to be unable to perform any work for which eyesight is essential, and as if for reference to "seventy" and "fifty" there were respectively substituted references to "fifty" and "thirty."

The Act further states that "it shall be the duty of every county and every county borough . . . to make arrangements to the satisfaction of the Minister of Health for promoting the welfare of blind persons ordinarily resident within their area, and such council may for this purpose provide and maintain or contribute towards the provision and maintenance of workshops, hostels, houses or other places for the reception of blind persons. . . . The expenses incurred by a council under this section shall be defrayed . . . out of the county or borough fund or rate."

It will be observed that the Act contains no specific arrangement for the certification of blind persons. Possibly those who drafted the Act considered that an applicant for a blind pension was in as good a position to provide a certificate of blindness as the old age pensioner was in providing a birth certificate. Possibly the "approved voluntary agencies" which administer the funds provided for the benefit of the blind might have claimed a grant for the purpose of certification from the Ministry of Health on the grounds of "necessity for securing the registration of all blind persons" (Rule 32, Ministry of Health Regulations and Rules for the Welfare of the Blind, August 7th, 1919).

As far as I know, however, this has not been done, and the local authorities have found it necessary, in the interest of the ratepayer, to get applicants for blind pensions or grants examined and authoritatively certified before the pension or grant is allowed. The Ministry of Health is very exacting with regard to the certification of trainees, and demands a medical certificate giving the visual acuity in each eye, the nature and extent of the visual defects present, and a definite opinion; formed after due consideration of all the visual conditions, that the person is too blind to perform work for which eyesight is essential. The local authority in Birmingham only requires a statement that the applicant is or is not blind within the meaning of the Blind Persons Act. That there is need for caution and discrimination in the administration of this Act is shown by the fact that a sum of £10,470 was distributed in weekly and special grants by the voluntary agency in Birmingham last year. The number of pensioners is rapidly increasing. In Birmingham in 1919 the number of adult blind living in their own homes was 425, whereas this year they number 1,005. When it is remembered that since 1928 every blind person may have his income made up to £1 a week, it is obvious that the expense to the community will be very considerable, and I think that the certification of blind pensioners should be no less detailed and comprehensive than that demanded by the Ministry of Health in the case of trainees. Since 1928 the number of applicants has more than doubled as compared with the years 1924-27.

The purpose of this paper, however, is not in the main to criticize the Blind Persons Act and its administration, but to analyse the causes of blindness in 700 old people as certified by me for the local voluntary agency in Birmingham during the last four and a half years. I have

* Read in the Section of Ophthalmology at the Annual Meeting of the British Medical Association, Manchester, 1929.

classified them into eighteen groups, and record them as follows in order of frequency.

700 Consecutive Cases Certified as "Blind Persons."

	No. of Cases.
Cataract	205
Atrophy of optic nerves	78
Glaucoma	75
Iridocyclitis and keratitis	54
Corneal opacities	45
Retinitis pigmentosa	43
Choroido-retinal atrophy	42
Congenital defects	33
Detachment of retina	27
Myopia	20
Phthisis bulbi	17
Choroido-retinal vascular disease	14
Diabetes	12
Ophthalmia neonatorum	9
Sympathetic ophthalmia	9
Trachoma	9
Buphthalmos	5
Injury (double)—two gunshot and one explosion	3

Cataract.—We are not surprised to find cataract at the top of the list. More than a sixth of the number were secondary, and these should be included under some inflammatory or degenerative disease. Of the ordinary senile cataracts over 37 per cent. were certified as operable, but so far as I know this in no way affects the granting of the pension. Neither do I know what may happen if such a patient gets his cataract removed and regains sufficient vision to enable him to do work for which eyesight is essential.

Atrophy of the optic nerves, coming second in the list, is unexpectedly high; 13 per cent. of these were of specific origin, and 10 per cent. were due to cerebral disease; the others were of unknown origin.

Glaucoma is a close third. Most of these appear to have been primary, only ten being recorded as secondary. About 10 per cent. of the former had been trephined.

Keratitis and iridocyclitis were mostly of specific origin (50 per cent.). In view of the fact that a number of the cases of atrophy of the optic nerves and choroid could also be ascribed to the same cause, it is obvious that syphilis constitutes the chief venereal factor in the causation of blindness in old age. It is to be hoped that modern preventive and curative treatment will do much towards reducing this high proportion of blindness from syphilis.

Corneal opacities form a rather ill-defined group. Most of them were of unknown origin. Some were associated with nystagmus, and were probably due to ophthalmia neonatorum. Some appear to be cases of interstitial keratitis, and a good many were associated with cataract.

Retinitis ... ...

the pain can, however, be followed with accuracy in the particular area that is being treated, and it is this fact which makes the observation so very useful.

The fact that the pain caused by this chemical cauterization of the endothelium is not felt immediately would seem to show that the endothelium is devoid of nerve endings acutely sensitive to pain. Schafer[1] says of the larger arteries and veins that

"nerves are distributed to the muscular tissue of the middle coat after forming a plexus in the outer coat. Most of the nerves are non-myelinated, but there are a certain number of myelinated fibres intermingled with the non-myelinated and passing to end in localized arborescences partly in the adventitia, partly in the intima. These myelinated fibres are doubtless afferent, the majority of the non-myelinated are probably efferent and derived from the sympathetic (vasomotors). . . . The capillary vessels also receive non-myelinated nerve fibres which have nuclei upon them and form a fine plexus of fibrils in close contact with the endothelial cells of which the walls of these vessels are composed."

The contraction of the vein frequently noticed by those who practise the treatment may be connected with the stimulation of the arborescences. So far it has not been possible to establish a definite connexion between the contraction and the onset of pain; first, because the pain moves onwards and becomes diffuse and the position of the patient's limb is changed accordingly, as will be described later; and secondly, because the colour of the partially empty vein, as seen through the skin, alters when the colourless solution enters it. A further complication is caused by the alteration in blood content when the tourniquet is removed. These three factors combine to make any accurate observation on this point difficult.

The nature of the delayed pain has been described by the patient afterwards as stinging, burning, cutting, boring, lancinating, shooting, cramp-like, creeping, cooling, and by one patient as the feeling he had experienced when a dentist injected his gums. Usually it is simply pain, and seems to be independent of the temperature of the solution. As a rule its onset can be noted with ease, and each patient is told about it beforehand and asked to say or to indicate where it is travelling, and at what rate. When the pain is sudden and severe every effort is made to dilute the solution with blood by a rapid change in position, according to Brodie's[2] (Trendelenburg's[3]) description, because this sudden onset often means an excessive and diffuse inflammation in the tissues round the vein at a later date. In such a case the veins are apparently easily permeable, but not necessarily very thin-walled. On the other hand, when the pain is of slow onset and slow cessation the change of attitude may be made correspondingly slowly; the solution may, as it were, be nursed along the course of the vein, even milked along it by the fingers. The ultimate result in the latter type of case is invariably the best obtainable. Moreover, it is particularly in this type that one can guide the course of the solution upwards or downwards, inwards or outwards, or in a combination of these directions. One may notice that a tributary area has been missed and be able to fill it with the solution still left in an adjacent vein. It occasionally happened that such an obviously missed area, which remained free from pain, was found later to have no occlusion of its veins. This observation suggested the great importance and the constancy of the deep communicating vein just above the knee, and so led to an alteration in the technical application of the method. It will be remembered[4] that in this method the solution is injected (when the case is suitable) into the saphena in the thigh with the vein empty and the patient recumbent; the patient then rises slowly and the solution travels down. Sometimes it misses one of the main tributaries just below the knee. Often it either misses, or its dilution has become too great to cauterize, the endothelium of the important loop or loops formed in the lower third of the leg between the internal and external saphena veins.

The bolus method has therefore been altered, and the injection is now more often given into a suitable vein on the inner side of the lower third of the leg and allowed to travel upwards. In the course of about forty to sixty seconds the patient indicates that it has reached the middle of the thigh; the limb is inclined downwards, over the side of the couch, and he says, "It is going down now to the ankle, foot, toes." Then the limb is placed horizontally again or elevated slightly, and we know that the solution at that moment is in the internal saphena from the middle of the thigh to the ankle. These alterations are made quickly or slowly, and of greater or less extent in exact accordance with the signs given by the patient. If by chance the patient is able to show quickly that one area has been missed, the limb may be re-inclined and the patient made to stand up, and if necessary to cough, in order to blow the now rather dilute solution into the mouth of the missed tributary. On the other hand, when it is evident that the solution is not travelling up the thigh, but only as far as the knee, the limb is elevated more and more and with an increasing degree of rapidity until it is vertical. If there is then no pain in the thigh the patient is quickly told to breathe out deeply so as to suck the solution up the thigh, a practical expedient based directly on Barber's[5] observation. In one patient with an enormous collection of varicose veins of the internal and external saphena systems the onlookers clearly saw the respiratory excursions in a vein over the patella. In slighter cases the movements may be shown by shining up the skin with glycerin, just as one may easily demonstrate a doubtful pulsation in a cranial defect, or the pulsation of one's own superficial palmar arch. Failure of the bolus method appears to be entirely due to the deep communicating veins sucking away and diluting the solution, and it is here that a previous acquaintance with these veins in the dissecting room, and especially an operative experience, is so valuable. When Gray's modification[6] of Babcock's extraction method was used the tributary sites were easily seen and counted on the extractor. Next in importance to the single deep connexion just above the knee, if not actually more important, is the one just below it, which joins the inner sural veins. This latter connexion may be multiple.

During extraction operations (or during the excision of a varicose ulcer) under fairly deep general anaesthesia the blood flows *from* the ruptured communicating veins and tends to form large collections in the subcutaneous tissues. It was therefore common practice to press on these areas after the extractor had been removed and thus to limit the flow. When the conscious patient uses his muscles, even feebly, it is highly probable that the blood flows in these junctions from the superficial to the deep system; *x*-ray observations are said to confirm this. Once in the deep system the dilution is excessive, both on account of the total area of the cross sections of the veins and of the rate of flow of the blood. No pain is felt nor is any obliterating effect produced. In no case has the patient later suffered from an added cramp, and in only three cases from cold feet, as a result of the treatment. In the majority of patients these two symptoms when present have invariably been cured, as have also the other symptoms of tiredness, weight, and the sense of fullness and bursting. Blueness of the limbs improves rapidly, but seldom entirely disappears. It appears, therefore, that the entrance of the solution into the deep veins is a matter of no importance except possibly medicinally. Its dilution in this way will account for any failures to produce thrombosis. There is no need to blame the solution.

It is said that the brown solutions of salicylate must on no account be used, but the reasons are not clear. The colour is sometimes due to a slight iron contamination from the glass, with possibly an added oxidation. On one occasion a hundred ampoules were found to contain brown solution, some of which was a very dark brown; all this solution was used with perfectly good results.

Another argument may be employed to show the absence of sclerosing effect on the deep veins. A history of white leg is quite rightly regarded as a contraindication to any obliterative treatment of varix, though not an absolute contraindication. After a time there may be evidence of a re-establishment of the deep circulation, and the oedema may partly subside. In such a case, if varicose veins should develop, it is a question whether or not these veins should be treated by sclerosing methods, wholly or in part. If

the symptoms are increasing or an ulcer is forming, it is advisable to make a preliminary test with a course of Unna's paste bandages applied from foot to knee with the limb emptied of blood—that is, after it has been elevated to 30 degrees for, say, twenty minutes with the patient's trunk and head horizontal. This is in all cases by far the most efficient way of applying the casing. It may at first seem puzzling that the foot never becomes strangulated. If the experiment is tried with an elastic bandage it will often be found to cause strangulation; in perhaps half an hour the foot will become painful, and then numb, blue, and cold. The Unna's paste bandage, being in no sense elastic, but forming a semi-rigid casing, does not contract on to the limb or exert greater pressure as the swelling increases. It exerts only a constant pressure, probably rather greater than the diastolic pressure, on the surface of the limb, and this is insufficient to compress the deep veins. In such circumstances the oedema subsides in a few months, and the skin becomes supple, especially round an old ulcer. At this stage it is safe to discard the Unna's paste for a lightly applied open-woven elastic webbing of a good but slight degree of elasticity. Two or three months later, if the improvement *is maintained, it may be taken as an indication for* sclerosing the main portions of the varix. Three such cases have been treated in this way, and as a result there has been considerable improvement in the tone of the water-logged limbs. Had the solution caused further deep thrombosis the results would have been bad.

The pain caused by the solution of salicylate decreases in severity as the fluid in its passage becomes more dilute. This is well seen in the multiple ladder pattern veins at the back of a thigh. In a case of multiple telangiectases the patient first described the sensation as painful, and then as a "creeping outwards" into the finer tributaries. The pain varies greatly in intensity in different patients and in different veins in the same patient. It may differ in veins of apparently the same size and in similar veins on each side. Wherever it is felt sclerosing changes inevitably follow, and where it is not felt it is uncommon for more than a local thrombosis to occur. In a few exceptional cases a considerable length of vein may become obliterated when little or no pain has been experienced, and it is noteworthy that the process is then relatively slow. In cases of telangiectases, especially in those arranged in separate clusters, the immediate effect is often most striking and the subsequent spread of the sclerosing effect convincing. As the blood volume of an injected vein decreases so the pain of a further injection becomes more severe. It may travel further and may last slightly longer. By observing the effect at fortnightly intervals it is apparent that sclerosis continues actively for at least nine weeks.

The solution used when the method was first tried (20 per cent. sodium salicylate, 10 per cent. saline) was apt to produce a thickened vein and not an obliteration, except in the smaller veins, or at the site of injection, and for a few inches only. Sometimes it would produce thrombosis in the bays of the varicosities, where the current was sluggish, and leave the main stream liquid. A 25 per cent. solution (10 per cent. saline), given also in larger quantities, was found to yield better results, and to-day the standard first dose for a medium-sized vein is 5 c.cm of 30 per cent. solution (10 per cent. saline), and for a vein of large blood volume 7 c.cm. of 40 per cent. solution (10 per cent. saline), each given with the limb emptied of blood and usually from below upwards. Dr. R. D. Macrae, when he was a dresser, suggested putting segments of the vein on the stretch in one direction during the injection so as to snaffle the communication to the deep anastomotics. This method is most useful in the thigh, where it is not infrequently followed by a somewhat delayed but sudden onset of sharp pain. One might expect this phenomenon from a study of the loops which are present in this situation and which are so well shown in Gay's[7] plates. These loops hold the solution and then allow it to pass into the superficial veins, where it produces pain. It may, however, pass away rapidly, or slowly and painlessly, into the deep circulation. The not uncommon failure of the bolus method from above downwards, and its great and frequent success when employed from below upwards, are also partly accounted for by this peculiar anatomical arrangement.

When most of the leg veins have become obliterated, and parallel anastomotics alone require injection, a useful means of access may sometimes be found in the dorsal veins of the foot. One should, however, be cautious in using veins in front of the ankle-joint or at the back of the knee where movement is frequent, because necrosis seems to be more readily caused in these situations. Injections into the external saphena should also be more dilute, or used in smaller quantities and more slowly than into larger veins. Throughout it is important to remember that the surface area of a cross-section of vein varies with the square of the diameter.

Technique.

In difficult cases the injection may be given with the patient standing or sitting, and into almost any part of the vein, remembering that in the smaller veins the valves are usually still efficient and the blood current towards the trunk. In the great majority of cases, however, the injection has been given with the patient recumbent. A good light, preferably an overhead one, is essential. For the particular method used it is convenient to have a low couch (18 inches high) on which the patient can stand for inspection, and from which, when lying, he can easily tilt himself up and stand on the floor. This height is also convenient for the injector when the limb is raised to empty it of blood. The patient stands, a band tourniquet is lightly applied and clipped, and he lies down. The lowest easily available vein is chosen and entered, and blood is allowed to float up to the plunger. The tourniquet is then loosened, the limb raised, and the injection given. By injecting the spare blood at the end of the plunger there is less risk of withdrawing salicylate solution through the puncture hole. The needle is withdrawn and pressure made over the spot. The changes in posture are then carried out as already described. Only one injection is given at each attendance. The limb should be kept bandaged *night and day* with a light elastic webbing for a fortnight or longer. The results since this procedure was adopted have been much better than formerly; there are fewer and smaller lumps afterwards, and what may be called *the stiction effect*, or immediate obliteration, is more often obtained. In the bolus method a large needle naturally gives a better result than a small one, the object being to spread the solution rapidly over the whole system before dilution occurs. In medium and small veins, however, the differences are not great, and here even a small injection, such as the quinine solution administered slowly, may, in a sluggish vein, give a thrombosis from ankle to groin. Usually, however, the thrombosis produced by the quinine solution seems to be only a few inches long. Many injections are required, and there is no definite means of controlling the extent of any one of them or of guiding it to the required distribution.

The salicylate-saline effect can, in the main, be judged after a fortnight. When both limbs are affected the injections may thus conveniently be made weekly and alternately; this allows time for the reaction to subside on one side before it begins on the other, and no great inconvenience is felt. In three cases only have the patients been off work—in one case for three days, in another for a week, and in the third for ten days. All were able to walk during these periods. When it appears that the case will be successful the patient should cease attending for an interval of two or three months. The result can be judged better in this way, and any further injections can be given later if necessary. The stiffness in the fibrous cords may take up to about six months to disappear, especially at the knee.

Necrosis.

Should solution escape from the vein the hole may be pricked at once with a Bard-Parker blade and gentle pressure made at a little distance around it to promote evacuation of the solution. The patient should rise to encourage bleeding, for if bleeding occurs necrosis is unlikely. Apart

from lack of skill there are many causes of a faulty injection, the most frequent, in my experience, being a blunt needle and a horizontal instead of an overhead light. A blunt needle may lead to imperfect puncture, or, if the guarding finger allows it, to a double puncture. In the latter event the operator, when dealing with a large vein, may wait for the distal hole to close and give the injection slowly, or he may safely give the injection in another part; but in dealing with a small vein it is safest to use the Barber's needle with a lateral eye. A lateral tributary may rupture from slight pressure (Barber[10]); a partially thrombosed vein also is often difficult to puncture, even with a small needle, and so is a very mobile one.

Necrosis of the vein itself may occur at or near the site of puncture from too long contact with the solution. Here again the Barber needle will help, because it can be rotated and thus used for spreading the solution over different parts of the wall. It is probable that necrosis of the vein wall, especially in thin veins, often occurs without being seen. In relatively superficial veins it is visible through the skin, and takes about three months to fade. Necrosis into the wall of a large vein is apt to be dangerous; one such case has been heard of in which severe secondary haemorrhage occurred. Necrosis into a vein occurred twice in this series, the longer being 1¼ inches, presumably due to the solution travelling along the adventitia. The vein in each case was firmly thrombosed, and no anxiety was felt in allowing the patients to work and the necrosis to run its ordinary course, whereby it exfoliated and the ulcers healed. The necrosis, like dry gangrene elsewhere, is easily treated by the patient with boric powder. When a line of demarcation begins a few drops of glycerinum acidi borici twice a day, on boric lint, until the ulcer is clean, followed by red lotion or a brilliant green dressing, is all that is necessary. Klapp's suction cup seemed to help in one case at the stage of separation of dead tissue.

In one case, not included in this series, excision under local analgesia was tried, with no gain in time to the patient. If, however, a plastic operation is possible as well, the gain in time in healing a large necrosis might be considerable. In the leg it is seldom possible to excise a large necrosis without producing deformity, and excision of a small necrosis may not be considered worth while. Though no evidence is advanced, excision is perhaps more dangerous than leaving well alone. In this series the duration of the necrosis has been approximately proportional to its volume; healing times (in months) have varied from 5½ months to about a fortnight. Fortunately necrosis is generally painless and is becoming uncommon, but the possibility of its occurrence is the chief drawback to using salicylate solution at the present time. By ascertaining as far as possible that the whole of the eye of the needle is in the vein, by injecting only when there is an entire lack of resistance to the needle and absence of pain, by watching for blanching and thickening in the surrounding tissues, and above all by practice, the risk may be considerably reduced and the extent of the extravasation kept down But in spite of everything going well an apparently inexplicable necrosis may mar an otherwise good result.

Results.

The results in the first consecutive series of completed cases treated by me at the Aberdeen Royal Infirmary by the bolus method (chiefly from below upwards) may be set out as follows. First the expected result of each injection, as indicated by the pain, is recorded in one of three divisions: maximum effect, good, and partly. A negative effect in these observations becomes a positive one in recording the result, because when there is no pain no thrombosis is expected. The observations for each limb are then added up and the total expected result recorded. At first the importance of pain as a guide was not appreciated, and in consequence the individual injection records are incomplete in a very few cases. This fact does not materially affect the total expected results. Secondly, the final result is given. For this purpose the limbs have been grouped into those in which the veins were enormous, very severe or very large, severe, marked, medium, and slight. While the symptoms often correspond with the signs, this is not always the case, and as at present we are estimating the sclerosing effect only, the signs have been taken as the guiding factor in assessing the results.

Number of patients treated	150
Limbs injected	243
Necrosis cases	24
Stiction effect	15
Patients previously operated on for varicose veins...	4

Degree of varicosity and number of injections:

Very severe ...	5 limbs,	requiring a total of	24	injections
Severe ...	31 ,,	,, ,,	152	,,
Marked ...	93 ,,	,, ,,	284	,,
Medium ...	82 ,,	,, ,,	174	,,
Slight ...	27 ,,	,, ,,	27	,,

Totals ... 243 limbs, requiring a total of 661 injections

Average number of injections per limb 2.7.

Results indicated by the pain experienced:

Maximum effect	101
Good effect	100
Partly	42
	243

Final Results.

Condition.	Perfect.	Excellent.	Very Good.	Good.	Fair.	Total.
Very severe	2	3	—	—	—	5
Severe...	6	17	8	—	—	31
Marked	34	56	7	—	1	98
Medium	38	33	9	2	—	82
Slight	16	9	2	—	—	27
Totals	96	118	26	2	1	243

It will be seen that for the very severe type of varix about five injections are necessary, and the same is true for a slightly less severe case. In these cases the veins are of large volume, tortuous, show a marked impulse to the ankle on coughing, and are very numerous. In the worst type the varicosities evidently join the deep veins at short intervals all over the limb, and more than the average number of injections are necessary. Thus in three such cases the numbers and strengths of the injections have been as follows:

	Right.	Left.
Case I ...	Six (20%), seven (30%), two (40%)...	Four (30%)
Case II ...	One (30%), one (40%)...	Five (30%) / Five (40%)
Case III ...	Five (20%), three (30%) / Four (40%)	Three (40%)

In each of these cases the degree of varicosity appeared much the same on the two sides, yet the number of injections differed greatly; they were the only cases in which numerous injections were required. One can sometimes surmount the difficulty by stopping the venous circulation both above and below with two band tourniquets while directing the distribution of the solution. There is an element of chance in this type of case which is difficult to get over. It is clear, therefore, that the best course is to try to prevent the occurrence of the severe types with multiple deep connexions by treating the limbs while they are in the earlier stages of varicosity.

In the marked type not more than about three injections are needed, in the medium type two, and in the slight type only one. It appears that the number of injections required in comparable limbs when other methods are employed is much greater than by the controlled method described.

In general, the symptoms have disappeared with the obliteration of the veins, but in some cases they have gone first; in a very few cases symptoms have persisted in minor degree after the veins have become firmly sclerosed. Mostly, however, the patients are greatly relieved and are better able to work. They often say that their shoes feel loose or that they require a smaller size than formerly. In some cases there is a distinct stage of slight swelling of the ankles which persists for about two months and gradually goes away as the new

circulation becomes efficient; this process is accelerated by using an elastic bandage locally at night. The feet may be swollen in the morning and the swelling subside after a day's work, thus affording interesting evidence of the action of the muscles on the deep circulation. The muscular tone improves greatly, but it has not been actually measured. Measurements by a tape on different days are apt to be misleading, but are sometimes useful if, on the same day, a comparison is made between a treated and an untreated limb. When all symptoms and signs are absent and the health is improving the final result has been assessed as perfect; then follow excellent, very good, good, fair, and failure. A family history of varix does not seem to affect the result, but varix when familial tends to increase. Speaking generally, in the severe types the older the patient the better the result. The oldest male to be treated was 75, and the oldest female 74. The man had enormous multiple varicosities from groin to ankle, and said that he had spent £170 on elastic stockings during the last thirty-five years; his work as a blacksmith had been hard on them. Eight injections cured the right and four the left limb.

Curious coincidences have been noticed here and there—for example, symptoms of dizziness, deafness, and light-headedness, especially in old persons, have cleared up. Whether the obliteration has a definite effect on the blood pressures or not, especially on the diastolic pressure as one would expect, will require to be worked out. If it has, then the method may have a wider application than it has at present.

Two cases in this series merit attention.

CASE I.

The patient, a man aged 56, was treated for varicose ulcer of the right leg, and an enormous condition of varicosities of the whole of both lower limbs. The ulcer at this time was nearly healed. Six injections of 40 per cent. salicylate (10 per cent. saline) from January 2nd until April 4th resulted in complete obliteration of the varices on the right side. On April 27th the *first injection of 40 per cent. salicylate* (10 per cent. saline) was given on the front of the left leg. A maximum immediate effect was produced. The patient went to work for a week. On May 5th he had pain in the back and chest and did not go to work. There was no cough or sputum, and no history of shivering. He remained in and out of bed, and on May 9th was admitted to a medical ward suffering from acute bronchitis, which was considered to be influenzal in origin as there was an epidemic at the time. Moist sounds could be heard over the whole of the chest. The patient died on May 10th. No post-mortem examination was allowed.

CASE II.

This patient, an unmarried woman of 32, was under treatment for a medium degree of varicosity of the left side. On February 23rd and March 9th injections of 40 per cent. salicylate (10 per cent. saline) were given. A medium immediate effect was obtained. On March 13th the patient had a right-sided hemiplegia from which she has made a good recovery. A sister had previously also had a hemiplegia. There was no gross cardiac disease.

These two are the only cases in the series in which any serious complication could be considered as possibly due to the treatment.

Conclusions.

Finally it appears in the light of the clinical results that the descriptive anatomy requires amplification. We want to know from injections and sections of the limbs in the dead subject the relative blood volumes of the superficial and deep veins in health and in conditions of varix. A plethysmographic record in old cases of white leg would help to tell us the carrying capacity of the deep veins.[9] The pain seems to be due not to the saline in the solution but to the salicylate alone. If those who use the saline method would try it with small additional strengths of salicylate added, it might be possible to find an ideal solution which would produce the maximum sclerosis, and only a slight but definite tingling at the time of injection.

In my experience the results of using local analgesics in the salicylate solution have, while allowing as far as possible for the unknown factors in the deep circulation, been entirely negative. As Barber[11] points out, their use might prevent the recognition and rapid evacuation or dilution of an extravasation. At present it seems clear that no great advance will be made until we have records of consecutive cases kept by different injectors on some comparable system and observed at greater leisure than is usually possible in busy hospital departments. The fact that in the majority of cases we can give in advance an approximate estimate of the number of injections required and can tell the probable distribution of the sclerosis makes the salicylate-saline method a very good one.

SOME OBSERVATIONS ON BERI-BERI.

BY

ALEXANDER CANNON, M.D.Leeds,

TEACHER OF MORBID ANATOMY, UNIVERSITY OF HONG-KONG; PHYSICIAN, COLONIAL MEDICAL SERVICE.

The following conclusions have been formed as a result of two years' research work on over six hundred patients of Chinese nationality, and more than eighty post-mortem examinations, as well as animal experiments.

1. Beri-beri is a syndrome of the Orient, confined to Orientals, chiefly males; seasonal in occurrence; prevalent during the wet season; partly infectious; a rice "disease"; and is brought about by three factors. They are: (*a*) water-soluble vitamin B deficiency; (*b*) a bacterial infection, closely resembling or identical with the *Bacillus asthenogenes* of Bernard (1919); and (*c*) endocrine organ disturbance.

2. A low cholesterol content of the blood is also essential to the occurrence of this syndrome.

3. The diagnosis and prognosis can be assisted by *x*-ray examination.

4. The pathology is specific.

5. Bernard's complement fixation test is a valuable aid to diagnosis.

6. Beri-beri may be either acute or chronic. The "dry" and "dysenteric" beri-beris are really camouflaged forms of malaria, as proved by the invariable findings of the specific malarial parasite on every careful examination.

7. The blood pressure and the cerebro-spinal fluid pressure have definite constant variation. In acute cases the blood pressure is always below normal, about 80, and the cerebro-spinal fluid above normal, about 200.

8. Magnesium sulphate, given daily in doses amounting to 150 grams, administered as twenty-four half-hour doses during the twelve waking hours of the day, and repeated, if necessary, on the two following days, together with 1/2 c.cm. of pituitary extract (B.W. and Co.) twice daily; also hypodermic injections of 1 c.cm. of a 5 per cent. solution of cholesterin in olive oil, given on alternate days for six to ten injections, bring about speedy amelioration of the symptom and sign complex; and, with the addition to the diet of vitamin B, complete the cure. Bernard's serums can also be used with good results.

9. Patients with beri-beri can take a large amount of sugar without it appearing in the urine, their capacity being about twice that of a normal individual.

10. The syndrome occurs almost solely in males; there are a few exceptions to this, as to every rule, but they are very rare. It comprises the following manifestations:

(1) Swelling of the feet: in China the complaint is known as "ker' k'i," meaning humidity of the feet.

(2) Swelling of the face: especially under the eyes, as in kidney disease (acute parenchymatous nephritis does occur).

(3) Swelling of the abdomen—ascitic.

(4) "Swelling" of the heart: detected by clinical methods and *x* rays (Reinhard, 1916).

(5) The blood pressure is lower than normal, being inversely proportional to the "disease."

(6) The patients are unable to rise from the squatting position without help, or by the aid of "crawling up their legs" with their hands, just as a person suffering from pseudo-hypertrophic paralysis does (Willcox, 1915).

(7) Knee jerks are usually absent, but may be grossly exaggerated (Darling, 1914).

(8) Tenderness is elicited on deep pressure over the nerve trunks.

Other signs and symptoms which may be present in a large number of cases are:

(9) Numbness of the feet.

(10) Bad taste in the mouth in the morning: probably caused by the resultant dilatation of the stomach owing to its asthenic condition.

(11) Respirations are shallower than normal.

(12) Vertigo may occur.

(13) The patient may complain of severe pain in the legs.

More remote signs and symptoms observed are:

(14) Sensation of faintness.

(15) Loose motions.

(16) Inability to walk.

(17) Slow pulse in convalescing cases.

(18) Skin whiter than normal.

(19) The respiratory quotient does not exceed 0.8 and is often only 0.7 (normal 0.9 to 1.0).

(20) The blood urea is usually 1 gram or more per litre of serum (normal is under 0.5).

THE CAUSAL FACTORS.

Three causal factors have been cited; they are as follows.

1. *Vitamin B Deficiency.*

The works of Funk (1911), Fraser and Stanton, McCarrison, and many others strongly favour this as a cause. The pericarp of "red" rice contains vitamin B. Darling's work in 1914 lucidly explains the relationship between beri-beri and other deficiency diseases as revealed in Fig. 1. Woolard[1] produces evidence strongly in favour of the deficiency disease theory. I have also satisfied myself that the bone conditions are similar in appearance in the various deficiency diseases.

The three important processes of growth in bone are: (1) growth and ossification of the cartilage between the

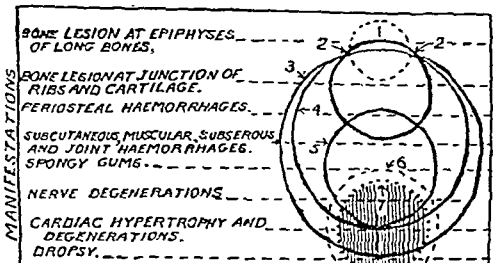

FIG. 1.—Diagram showing the relation of beri-beri to other deficiency diseases. The circles from above downwards represent: 1, rickets; 2, infantile scurvy; 3, scurvy of guinea-pigs (large circle); 4, scurvy (smaller circle); 5, ship scurvy; 6, polyneuritis avium; 7, beri-beri. The shaded portion indicates the position of beri-beri.

epiphysis and shaft; (2) enlargement of the marrow cavity, which is effected by absorption of the inner layers of the shaft; (3) increase in thickness of bone due to deposition of bone by the inner layers of the periosteum. In rickets, which occurs in early life, the process in (1) is exaggerated; in (2) it is more rapid than usual; whilst in (3) the growth is defective and uneven. This results in a larger medullary cavity and a thinner shaft than normal, but a great excess of cartilage at the epiphyses.

Now beri-beri ("infantile beri-beri" is not included as it is another disease) occurs in adult life, when the normal processes have continued until the onset of the syndrome; this results in an enlarged medulla at the expense of the thickness of the shaft bone, but cartilage growth, which has long since ceased, remains unaffected by any degenerative process.

2. *A Specific Bacillus.*

This is probably the *B. asthenogenes*. My colleague C. Y. Wang, professor of pathology in the University, states that "this organism gives all the essential characteristics of the *B. cohaerens* of Göttheil." Elsewhere[2] I have given the full bacteriology of this organism, and experimental proof of its relationship to beri-beri. Suffice

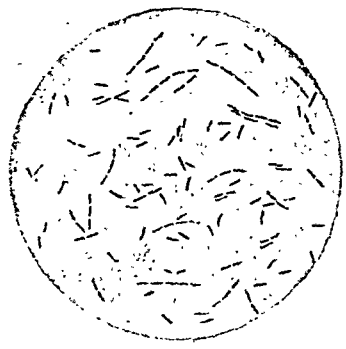

FIG. 2.—The *Bacillus asthenogenes* of Bernard. Bouillon cultures twelve hours old (anaerobic and aerobic).

it to say that it exists in two forms: aerobic and saprophytic in the presence of vitamin B; and anaerobic and pathogenic in the absence of water-soluble vitamin B.

The toxin is obtained by filtering through a Pasteur-Chamberland filter candle No. 4. A 1 c.cm. dose of the filtrate injected into the vein of the ear kills a rabbit averaging 1,800 grams in weight. For research purposes Bernard concentrates this toxin and obtains a product which kills by a constant dose of 1/20 c.cm.

The bacillus can be isolated from human blood for anaerobic culture in a medium consisting of bouillon and milk in equal parts. Only when gastric symptoms exist and at irregular periods can the bacillus be found in the peripheral circulation. In cases of paralysis it is absent, just as the Klebs-Loeffler bacillus is absent in diphtheritial paralysis. It can always be found in the spleen.

Various serological researches are carried out by taking a culture of twelve hours' growth and centrifuging. The bottom of the centifuge is diluted with saline to 0.5 per cent. strength. The best culture medium is pork 25 grams and saline solution (0.5 per cent.) to 100 c.cm. The suspension should be sterilized at 120° C.; 15 c.cm. of milk is then added, followed by 10 c.cm. of a fresh culture (twelve hours' growth), and the whole is heated to 37° C.

The fixation of complement and agglutination test of Bernard is performed with the same culture. For agglutination an emulsion of the microbe is made in 0.5 per cent. saline solution, and is then adjusted to *pH* 6.5 and heated to 45° C. Agglutination occurs after five hours. For certain diagnosis agglutination only above 1 in 150 must be considered. (Other serums 1 in 50 and 1 in 100.)

3. *An Endocrine Disturbance.*

The relative mental dullness and possible myxoedematous appearance suggest an endocrine disturbance, as do the cases of insanity associated with beri-beri (70 in 290). As regards the morbid anatomy of these endocrine glands in beri-beri, the pancreas appears normal, but the islets of Langerhans are much hypertrophied; their function has been shown to be increased. The suprarenals are hyperaemic; there is hypertrophy of the cortex without degeneration, and the medulla is hypertrophied, with marked round-celled infiltration around the vessels; hyaline bodies are also present. (Comissati's chemical method estimates an increased secretion of adrenaline.) The prostate is congested and enlarged; the thymus is present and increased in size. The pituitary body is unchanged, and the

remaining organs are atrophied. (In all cases of sudden death, as in beri-beri, the thymus is enlarged.)

Low Cholesterol Content.

The Chinese normal cholesterol content is 0.62 (European 0.68). Women usually escape infection, probably owing to the regular menstrual cycle, which occurs about thirteen times yearly, each cycle being accompanied by increased cholesterol content of the blood. In gall-stone patients the content is raised, and I have never yet found evidence of beri-beri in a cadaver in which gall-stones were present (I examine about 1,500 adults and 2,500 children yearly).

X-Ray Diagnosis.

The pulmonary vessels and right side of the heart are enlarged first; then the left side of the heart enlarges. When convalescence commences, first the left side and then the right side clears up, and finally the pulmonary vessels resume their normal size.

*Post-mortem Landmarks.**

"Water here, water there, water everywhere" well describes the condition of the body. Rigor mortis is either very rapid or very slow in onset (normal average 4 hours onset to 36 termination).

The heart looks fatty, and the heart muscle resembles bad beef; the right ventricle may be three times the size of the left. The lungs, stomach, intestines, bladder, and spleen are congested and oedematous. The kidneys show acute parenchymatous nephritis.

The nerve changes fall into three groups: (1) Changes without interruption of continuity. These are analogous to cloudy swelling affecting both axis cylinder and medulla; found in early stages. The condition terminates in (*a*) complete restoration, (*b*) advanced degeneration, or (*c*) atrophy in course of time. (2) Changes with interruption of continuity. The nerve changes are not diffused but are localized in patches. All degrees of degeneration may be seen together, and the medullary sheath is fragmented. The continuity of the axis cylinder is not broken, but it may be charged with coarse and fine granules. There is little functional loss. (3) Atrophic changes occur later. The nerve bundles are greatly shrunken, with atrophy of the medullary sheaths. The axis cylinders are narrow and uneven, and the interstitial tissue is increased. Function is greatly disturbed. The arteries show irregularity of the tunica media, with spaces between the cells.

Blood count: finely granular oxyphils, 60 per cent., coarsely granular oxyphils, 5 per cent., basophil leucocytes 0.5 per cent., hyalines 20 per cent., lymphocytes 14.5 per cent.

The muscles show fatty degeneration, and there is often marked atrophy of the peroneals. Two forms of changes are to be differentiated: a primary change caused directly by the Kakke toxin, and a secondary one, the result of changes in the nerve supply.

The organs of the body have antineuritic powers in the following order: liver, heart, cerebrum, cerebellum, and voluntary muscle.

Oedema is most marked at the auriculo-ventricular junction in the heart. Atrophy is most marked in the testicles. Keratomalacia is found in some cases. Corneal opacity may suddenly appear and end in panophthalmitis. The administration of fat-soluble vitamin A quickly arrests this condition in the early stages.

In my opinion it is the vitamin deficiency which renders the body very liable to be overrun by the rank growth of bacteria, and this is the pivot upon which we should base our further researches.

I wish to thank Dr. P. Noel Bernard and his staff for their courtesy to me and kind help while in Indo-China and China; also Dr. C. Y. Wang for his confirmatory work on the bacteriological aspect of my researches.

ASPIRATING THE CONTENTS OF THE STOMACH.

BY

HAMILTON BAILEY, F.R.C.S.ENG.,

SURGEON, DUDLEY ROAD HOSPITAL, BIRMINGHAM.

WASHING out the stomach of a desperately ill but fully conscious patient ranks high among the most distasteful tasks in surgery; it is only natural to shrink from adding to the discomfort of the patient. Misdirected compassion, or fear of still further upsetting a patient who is already in a critical condition, may be determining factors in withholding the stomach tube in cases where it is strongly indicated—a form of conservatism which is often the antithesis of good judgement.

In those conditions where emptying the stomach may prove a life-saving measure the contents of the organ are known to be of a watery consistency; acute dilatation of the stomach, intestinal obstruction, and vomiting after gastro-jejunostomy are but a few of such conditions. The question which arises is, Why employ a large calibre tube to evacuate a watery fluid?

Ryle's small stomach tube (Fig. 1) can be swallowed without overwhelming discomfort and without shock. In the few patients who find that they cannot swallow the tube a little 10 per cent. cocaine sprayed on the pharynx will enable them to do so. Once the tube is in position the stomach contents can be aspirated with a syringe. A bladder syringe answers the purpose, but a well-fitting glass syringe, such as that shown in Fig. 2, makes for a perfected technique. After the contents have been aspirated the organ may be washed out with boiled water, or anything else which is thought desirable. No one who has had experience with the large red rubber tube, funnel, jug, and mackintosh apron would wish to return to them.

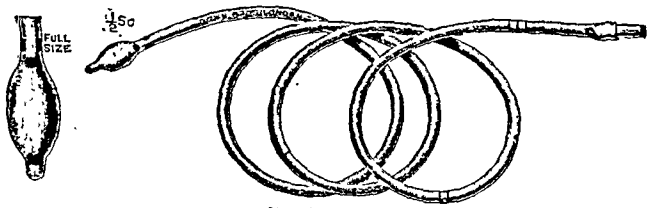

FIG. 1.

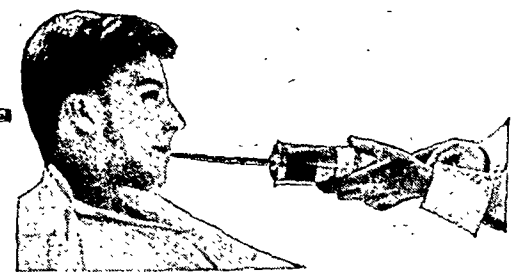

FIG. 2.

Speaking personally, I look back with a shudder on the older method, and every time I see the stomach contents being quietly and painlessly and effectively aspirated I experience a feeling of gratitude to Dr. Ryle for his invention.

Having once gained familiarity with the method one finds increasing fields of usefulness for gastric aspiration. Not only does the need for jejunostomy grow less, but there will be found occasions where the method may be employed as an aid to urgent diagnosis.

This note does not claim to express anything original; it is rather a plea for the more universal adoption of a very satisfactory principle.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

MOTORIST'S HEEL.

This note is prompted by the correspondence on the subject of painful heel in the *British Medical Journal* during the spring and summer. One important cause—motor driving—escaped mention, and I have not discovered any reference to its etiology in the literature.

The causes of painful heel may be classified as affections of: (1) the fibro-fatty pad; (2) the bursa beneath the tendo achillis; (3) the os calcis.

The Fibro-fatty Pad.—This thick pad, situated where the heel rests on the ground, is fairly sharply defined, especially behind, where it quickly gives place to delicate skin beneath which is little or no subcutaneous fat. Being relatively avascular it is liable to that class of affections in the wide category of "rheumatic." The well-known painful heel of gonorrhœa probably comes into this category, as does that due to dead and infected teeth.[1] When gout was prevalent the heel was not an infrequent seat for the development of tophi. If the focus of infection is discoverable its removal will result in a cure. The delicate skin on the back of the heel is liable to ulceration as the result of ill-fitting footwear, especially shoes. The skin is relatively fixed, and there is no subcutaneous fat to act as a cushion. The ulcers heal with difficulty unless the cause is removed.

The painful heel I wish to describe is not uncommon among motorists. I have known of three cases; a local garage man tells me he has come across at least a dozen. The history is as follows: The patient drives a long distance, either over a rough road or over a busy one, necessitating frequent manipulation of the clutch or accelerator. The following morning he finds that he is unable to put the heel to the ground owing to the pain, which may even have awakened him. There is exquisite pain over the whole of the heel pad, and a particular point of tenderness at the site of attachment of the plantar fascia. There are probably two factors contributing to the trouble. First, the heel rests on the floor-board in an unusual position—that is, on its posterior aspect, a tender area. Secondly, the manipulation of the clutch and accelerator in cars with a low floor-board necessitates keeping the foot in a fully dorsiflexed position. These two positions in the presence of vibration are sufficient to stretch the fascia, always a painful process. Abstinence from driving for a day or two will usually bring about a cure. A prophylactic measure, and one in constant use among lorry drivers, is the fitting of a board covered with matting or soft material beneath the controls.

Bursa beneath the Tendo Achillis.—This is liable to inflammation from footwear, especially shoes in which there is incurving of the heel; it may result from a blow. Rest and change of footwear will usually bring about a cure.

The Os Calcis.—Exostoses are occasionally found in the region of the epiphyseal line and may cause pain, especially if there is any dropping of the arch of the foot. At times ossification proceeds into the plantar fascia and is visible as a spine or process directed anteriorly.[2] If flat-foot should develop there is a tendency for this spine to be directed downwards, so causing pain. Treatment of both these conditions is directed primarily to the flat-foot; only if symptoms persist after its cure should operative removal be undertaken. Tuberculosis affects the cancellous bone and usually ends in caseation and suppuration with sinuses; small sequestra may be extruded. Syphilis may cause a gummatous periostitis which is very painful, but since the improvement in the treatment in this disease, bony manifestations are becoming relatively rare.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

UGANDA BRANCH.

Treatment of Ante-natal Syphilis.

At a meeting of the Uganda Branch on March 22nd, Dr. A. R. Cook, a C.M.S. medical missionary in Uganda, read a paper on the treatment of ante-natal syphilis in Baganda women.

Dr. Cook called attention to the problem of treating, with the means at their disposal, a very large number of cases of syphilis among the natives of the Uganda Protectorate. It was obvious that, merely from the financial side, methods which could be adopted conveniently for tens of cases among Europeans become impracticable when applied to hundreds of thousands. The five races—namely, the Baganda, Banyoro, Batoro, Banyankole, and Basoga—which formed the core of the native population were syphilized to an extraordinary degree, as had been recognized for many years. In 1907 the late Colonel Lambkin conducted an investigation, and, in the following year, a commission inaugurated an intensive ante-natal campaign, the first treatment centre being situated in Old Kampala; this station was subsequently removed to Mulago, and subsidiary country centres were started. The outbreak of war stopped the extension of treatment; on its resumption the problem had to be faced that the Baganda people had an extreme idiosyncrasy for mercury, and numerous deaths followed its intramuscular injection. In 1911 the original German salvarsan had been found to be very effective, and in many cases a single dose seemed all that was necessary. In 1921 it was estimated that 80 per cent. of the Baganda people had at one time or another suffered from syphilis; there were, therefore, a very large number of children with congenital syphilis. The native mother showed few signs of active disease, even while she was producing many abortions, stillborn infants, and congenitally affected children. The treatment of latent syphilis in pregnant women was therefore an urgent necessity in Uganda, and in the central institution (the Lady Coryndon Maternity Training School) and its twenty-two associated country maternity centres several thousand pregnant native women were being treated annually. The stock remedy employed was a mixture containing one forty-eighth part of a grain of mercury perchloride to the ounce of water, coloured by methylene blue; this was taken thrice daily throughout pregnancy. Dr. Cook claimed that this medicine, which had stood the clinical test of many years, was effective, cheap, readily taken by the natives, and without injurious after-effects. There were records of innumerable cases of women who, after a long series of miscarriages, bore healthy children for the first time after a course of this treatment, which was rapidly increasing in popularity; husbands often made a journey of many miles to obtain it for their wives, who were unable to walk the distance. This was clear evidence that the results were being widely recognized as highly satisfactory. The cost of the drug was negligible, and the patients were able to pay the expense; salivation was very rarely met with, and no other ill effects had to be considered.

Dr. Cook commented on the importance of the social life for these women which attendance at the treatment centres fostered. In the comparatively few cases where the pregnant mother showed active signs of syphilis intramuscular injections of salvarsan substitutes were combined with mercurial treatment, only one, or at the most two, being necessary. Arsenobenzol treatment was impracticable in Uganda, since the cost was prohibitive. In the case of infants suffering from congenital syphilis salvarsan was used, but mercury remained the sheet anchor. Dr. Cook thought that the susceptibility of the native to the action of mercury was worth investigating. He believed that the question was largely bound up with the almost universal immunity shown by the adult native to malarial poisoning after many attacks. The idiosyncrasy to mercury seemed to vary in different tribes, and infants could take relatively much larger doses than adults; the renal excretory capacity was possibly a factor to be studied in this connexion.

Reports of Societies.

ORAL SEPSIS AND GENERAL DISEASE.

IN the Section of Odontology of the Royal Society of Medicine, on October 29th, the incoming president, Mr. J. M. ACKLAND of Exeter, delivered his address from the chair, taking the subject of oral sepsis in relation to general disease.

After a reference to oral sepsis as the principal septic infection in medicine, and oral antisepsis as one of the most important and simple means of prevention of groups of maladies affecting almost every system of the body, Mr. Ackland discussed the commonest of all the groups of diseases arising from oral sepsis—namely, chronic rheumatism, arthritis, and neuritis. He believed that in cases of chronic rheumatism, where obvious foci of infection were present—for example, septic teeth—more harm than good must result from the use of vaccines, for these could not raise the immunity when such septic foci existed. Certain diseases, especially those leading to chronic inflammation of fibrous tissues and serous membranes, were more often associated with the sepsis connected with dead teeth than with a suppurating periodontitis. The type of streptococcus found in these cases—of neuritis, for example—was not the long-chained *S. pyogenes*, which was the streptococcus of acute suppuration, but *S. salivarius*, a short-chained variety, held up at the very root of the dead tooth; the pathological process going on there and leading to sclerosis was precisely similar to that which was taking place in the muscular fasciae and the sheaths of the nerve trunks. These cases of injury to health caused by dead teeth were very numerous, possibly more so than those of pyorrhoea alone; although it was a remarkable fact that many cases of pyorrhoea occurred in patients with absolutely sound teeth, there were necessarily many others where the two diseases coexisted. Dealing with anaemia and its association with oral sepsis, Mr. Ackland pointed out that there were two forms of severe anaemia: the haemolytic disease (idiopathic or pernicious anaemia), and a non-haemolytic or septic anaemia; the cause in no fewer than nine-tenths of these cases was pyorrhoea. Septic anaemia might exist alone, but far more frequently it complicated other anaemias in which similar conditions of oral sepsis were present; herein lay part of the great importance of oral sepsis in pernicious anaemia, which Dr. William Hunter had preferred to call "glossitic" anaemia, since soreness of the tongue was one of its earliest and chief diagnostic features. Another effect of oral sepsis to be borne in mind was in traumatic lesions, the setting up, for example, of a chronic synovitis after an injury to the knee; complete recovery followed the removal of the dental sepsis. Again, oral sepsis might penetrate the orifices of the parotid and submaxillary glands, and set up a chronic inflammation in their ducts and substance, though acute septic infection, which used to be common in the parotid and was often fatal, had now become rare, because one of the duties of the nurse attending exhausted medical and surgical patients was to keep the mouth as clean as possible. Another condition was Vincent's angina; no patient who had been under treatment for this affection should be discharged as cured until swabs from around the teeth were free from the fusiform bacillus which was regarded as the cause.

Septic conditions of the mouth favoured the occurrence of tuberculous infection by lowering the vitality and power of resistance. In the open-air treatment of phthisis too much stress could never be laid on the need for the mouth being in a healthy aseptic state. The human mouth was a perfect breeding ground for pathogenic organisms; it provided the conditions of temperature, moisture, and nutrient material, and although Koch's bacillus, apart from its presence in sputum from the lungs, was seldom found, the bacterial flora of the mouth contained pathogenic as well as non-pathogenic organisms. Mr. Ackland commented on the serious effect of oral sepsis in children, including its influence in retarding growth, in causing gastro-intestinal disorder, and in serving as a powerful predisposing factor in tuberculous infection. He mentioned a number of other troubles, such as middle-ear disease, septic bronchitis, and skin affections, which might be due to or influenced by oral sepsis. Dr. William Hunter had been a great pioneer in pointing out that oral sepsis and the multiple ill effects which it produced were facts of the first magnitude in medicine.

AVERTIN ANAESTHESIA.

A DISCUSSION on avertin anaesthesia was opened by Dr. JOSEPH BLOMFIELD in the Section of Anaesthetics of the Royal Society of Medicine, on November 1st, with Dr. ASHLEY DALY in the chair.

Dr. Blomfield said that avertin, a tribromethylalcohol, was a white crystalline substance soluble only with difficulty in water. For some time after it was introduced into practice it could be obtained only in the powdered form, but later the makers produced a standardized solution—fluid avertin—to which, before use, distilled water was added; the strength of the solution should not exceed 2.5 to 3 per cent. The dosage was governed roughly by body weight; 0.1 gram per kilogram (or about two-thirds of a gram per stone) was commonly employed. The technique of injection was very simple. From half to three-quarters of an hour before operation time the solution was introduced slowly into the rectum through an india-rubber tube, which should be passed up at least 4 inches. It was desirable that the anaesthetist should be present when the solution was run in, because the reaction of different persons varied. In one case apparently a perfectly safe dose was administered to a man aged 25, supplemented by gas and oxygen, since the avertin alone proved to be not quite sufficient for the operation; he failed to eliminate the avertin, and died eight hours afterwards. In his own experience the speaker had had nothing comparable with that, and he believed that there must have been, somewhere, an error of technique. In quite the early stages of the use of avertin, however, he realized that it was a particularly potent drug, and one to be employed with great care. Generally the induction of unconsciousness was extremely satisfactory; the rectal injection of avertin was as pleasant a way of inducing narcosis as could be found, and no excitement or evidence of discomfort was apparent. The respiration generally became somewhat depressed; it was rather shallower and slower, not unlike the respiration in sleep, except that there was a slight diminution of colour in the face and a very easy development of stertor. The blood pressure dropped by about 10 to 15 mm. Hg. The pupils were almost always quite small, and the eyes were stationary. The lecturer had found that in only about a quarter of his own cases did a satisfactory anaesthesia for operation follow the use of avertin only. Much depended on the character of the patient and of the operation. The class of case in which avertin had given most satisfaction was carcinoma of the oesophagus in elderly people who needed a gastrostomy; no other anaesthetic had been required. Cases of exophthalmic goitre were also suitable, and persons who had had a difficult experience previously with other anaesthetics. The average period of unconsciousness was from two to four hours, but the narcosis was not nearly so deep as that due to paraldehyde. He had not hesitated to use avertin in cases of operation on the tonsils where there was blood in the neighbourhood of the air passages. Dr. Blomfield concluded by expressing the view that, as a complete anaesthetic *per se*, avertin could not be relied on with any certainty, but as an introduction to anaesthesia it presented many advantages, and might be considered for certain types of patients the best agent available for securing a quiet advent of unconsciousness.

Sir FRANCIS SHIPWAY spoke from experience of the use of avertin in 106 cases at Guy's Hospital; in the forty-five earlier cases solid avertin was used, and fluid avertin in the remainder. For children he preferred the 3 per cent. to the 2½ per cent. solution; the disadvantage of the latter was the increased quantity of fluid which had to be taken. The patients were given an ordinary enema the night

before operation, if this was to take place in the morning. The patients included sixty-six males, of ages between 12 and 72, and forty females, of ages between 15 and 66; seventeen of the patients were over the age of 55. Estimation of the correct dosage was extremely difficult; the body weight was an unscientific and uncertain guide, because much depended upon the individual temperament and condition. The best that could be said was that certain types of patient, such as the alcoholic or the highly strung, reacted less readily than the placid. The doses averaged from 0.08 to 0.15 gram per kilogram of body weight, but his most recent patients had not had a higher dose than 0.10 gram. The maximum quantity of avertin given was 11 grams. A German writer had stated that in no case should more than 10 grams be given, but the speaker thought that a heavy man, weighing 15 or 16 stone, might have his full amount; as age increased the dose could be diminished. Sir Francis had not himself endeavoured to see more than a small percentage of the injections; up to the present there had been no cause for anxiety even when the full dose was given. He had used avertin in seventeen abdominal operations, also in cases involving the removal of the breast, and in operations on the nose and throat. In twenty of the cases avertin had been sufficient in itself; these included operations for haemorrhoids, also an operation for anal fistula in a man with active pulmonary tuberculosis. The combination of avertin with gas and oxygen seemed to be the ideal. The induction of unconsciousness was very easy; sometimes consciousness was lost while the patient was in the middle of a sentence. He had never had occasion in these cases to resort to a respiratory stimulant. The blood pressure fell generally about 10 mm. Hg, the maximum observed being 30 mm. He had noticed in five cases, either with avertin alone, or with avertin followed by gas and oxygen, the development of rapid twitchings with rigidity of the jaws and the arms; he had not encountered in any case irritation of the bowel. The period of unconsciousness following a small dose was about one and a half hours, and the patient afterwards went into a refreshing sleep. His conclusion was that avertin, if used with care at the dose recommended by Eichholtz, was a safe and valuable agent of induction, especially in highly nervous and overwrought subjects and in those who had suffered previously from other anaesthetics. He thought it was contraindicated in subjects suffering from renal disease.

Dr. JAMES YOUNG (Edinburgh) said that he had employed avertin in 154 unselected cases in his hospital and private gynaecological practice. This experience had led him and his anaesthetist, Dr. James Robertson, to regard it as possessing considerable value as a routine agent. It was superior to ordinary methods in the ease and comfort of the induction, the freedom from post-operative vomiting, and the freedom from the common post-operative respiratory complications. The absence of the straining incidental to post-operative sickness made avertin specially valuable in cases where the abdomen had to be opened, or where plastic operations were carried out on the pelvic floor. In the case of operations on the pelvic floor he and his colleague advised withdrawing the solution from the lower bowel before the operation was started. This was easily done by introducing a catheter after the legs were slung up on the lithotomy supports, and it obviated the soiling of the operation area by the fluid which was apt to be forced from the bowel when the posterior retracting speculum was introduced into the vagina. The withdrawal of the solution did not interfere with the anaesthesia. Dr. Young had found avertin of special value in hospital work in that a great saving of the time between operations was obtained. In his experience the recognized dangers of anaesthesia had not obtruded themselves; obstruction to the air passages by the relaxation of the jaw and tongue was easily overcome by the introduction of an artificial airway. In one case there had been considerable depression of the respiratory centre, which was at once removed by the use of carbon dioxide. The respiratory troubles had been less since the preoperative dose of morphine was restricted to one-eighth of a grain. In several cases a marked fall in blood pressure had been found, in one case by 50 points. In the series of 154 cases there had been two deaths: one after a hysterectomy for acute prolapse in a case of submucous fibroid of the uterus, and the other in a long-standing case of pelvic infection; in neither case could the death be attributed to the avertin.

Mr. H. E. G. BOYLE suggested that, if induction was so quiet and smooth, avertin might be used, not as an anaesthetic, but as a form of pre-medication to the ordinary anaesthetic. Dr. F. P. DE CAUX said that since he had been using avertin as pre-medication only he had found it of considerable value, especially in very nervous patients. He administered from 50 to 80 milligrams per kilogram of body weight, the higher amount for the very nervous patients, the lower being quite enough for the ordinary patient. Dr. C. F. HADFIELD commented on the excellent way in which avertin had been introduced into practice in this country. It had been realized that avertin was dangerous if not controlled, and, therefore, before it was placed on the market, a quantity was made available for a limited number of clinical trials; until the Anaesthetics Committee, of which Dr. Blomfield had been president, had reported, the manufacturers refused to permit the unauthorized use of the substance. This was a very good and proper method of introducing a new preparation which was of the nature of a dangerous drug.

Dr. Z. MENNELL said that this was a type of anaesthesia which, for a normal person, he disliked. In patients, after the administration of avertin, the respiration was undoubtedly depressed, and there was a certain amount of cyanosis. It seemed necessary to attend to the airway just as with any other anaesthetic. He was strongly of the opinion that the induction of avertin anaesthesia should not be left in the hands of nurses. Certainly its use as a routine would be a misfake, and the cases for which it was not suitable had still to be determined. Mr. GEOFFREY KEYNES had hoped that with the advent of avertin anaesthesia ordinary inhalation anaesthesia might be eliminated in abdominal operations. He had been particularly interested in the use of avertin in patients with exophthalmic goitre, where he had been in the habit of using a local anaesthetic. Very many patients were extremely apprehensive and went through a severe ordeal, although they usually stood it well. If their experience could be ameliorated by the giving of avertin it would be worth while. Mr. IVOR M. LEWIS, speaking from an experience of 28 cases, said that the patients on whom avertin had most effect were of the subthyroid type; those on whom it had least effect were of the hyperthyroid type.

Dr. BLOMFIELD, replying to a question as to the use of morphine or omnopon as a preliminary, said that he thought in most cases this could be dispensed with. Except, perhaps, in the alcoholic or some particularly resistant type of patient, a start could be made with 0.1 gram per kilogram, without any preliminary at all. Sir FRANCIS SHIPWAY, speaking also with regard to the preliminary use of morphine or omnopon, said that he had always been rather frightened of large doses of either drug. He believed avertin to be a safe anaesthetic for use with care and in selected cases. It was contraindicated in some cases—for example, when there was likely to be a rapid fall of blood pressure or much loss of blood.

AT a meeting of the Royal Society, on November 7th, Sir WILLIAM HARDY communicated a study by Dr. E. C. Smith on the coagulation of muscle plasma, including an account of the preparation and properties of a liquid expressate of muscle, representing as nearly as possible the living plasma. It was shown that gelation occurred in such an expressate only when a trace of a neutral salt was added to the finely divided muscle in a frozen state. Experiments indicated that such gelation and the hardening of the muscle in rigor mortis were one and the same phenomenon, change in the hydrogen-ion concentration being irrelevant to the process of gelation. Professor A. V. HILL, F.R.S., and Mr. P. KUPALOV contributed papers relating to the anaerobic survival in muscle, and the anaerobic and aerobic activity in isolated muscle. Professor HILL also reported observations on Olympic athletes made by Mr. C. H. Best and Miss Ruth Partridge.

Reviews.

"RADIUM PRACTICE, 1929."

During recent months post-graduate classes in the principles and practice of radium therapy have been given in London, both at St. Bartholomew's and at the Westminster Hospital. The teachers at neither institution pretended that they were making more than a statement for the moment of the position which they have reached. Finality and standardization are still far distant goals, but nevertheless the importance of the volume just issued by the staff of the Westminster Hospital, as volume xxi of their *Reports*,[1] can scarcely be exaggerated. In a book of 258 pages is contained an account by experts of every aspect of radium therapy, both theoretical and practical. It is wisely given the temporizing title of *Radium Practice, 1929*. The keynote of the writing is honesty of purpose—to give statement without overstatement, and to fill the learner with a wholesome sense of the difficulties and uncertainties which beset the path of the radium worker.

The members of the class at the Westminster Hospital were given a varied fare of twenty-six courses; the *hors-d'œuvre* introduced them to the general physical, chemical, and biological sides of the problem; the intermediate courses brought them down to the hard facts of the practical application of radium to the patients; the dessert tickled their appetites with an account of the possibilities of "teletherapy," which is the polite name for the use of the radium "bomb." The volume is edited by Mr. E. Rock Carling, who contributes an introductory lecture, an account of the treatment of sarcoma, and a short lecture on the radium "bomb." Even among so many matters of topical interest, the "bomb" will perhaps take first place, in view of the recent placing of 4 grams by the Radium Commissioners in the hands of the Westminster Hospital authorities. Mr. Rock Carling forecasts the possible applications of the method, and these include all the deeper sites of primary and secondary growth which cannot be reached by ordinary surface applications or by interstitial irradiation. Experience is at present too limited to allow of confident predictions, but warning is given that the metabolic disturbances, which often accompany any form of radium treatment, are at their maximum in teletherapy with the bomb. Effective irradiation of metastases in the liver is indeed impossible, owing to the effect of the rays on the normal cells of that organ. Mr. Rock Carling suggests that the administration of intravenous glucose may make possible a longer irradiation of the liver. This reference to the biochemical effects of radium immediately suggests reference to the chapter on this subject by Mr. F. D. M. Hocking. Here the thesis of a "precancerous toxaemia" is developed, and the possibility of destroying cancer cells by a temporary increase of the causative toxaemia. The suggestion is made that radium acts by the production of this toxin, and so a complete theoretical basis is found for the use of radium in curing cancer. Other arguments of a highly theoretical character are introduced, and these combine to make a stimulating chapter—which may have little relation to the truth, but is none the less valuable for that.

The important question of radio-sensitivity is discussed by Mr. Peter Kerley, who has gathered together most of the relevant facts. He emphasizes the importance of the metabolic rate of the cell as being the index of radio-sensitivity. Again, however, the question is so highly theoretical that little positive help emerges for the present. Mr. Kerley, in conclusion, points out that when we have found the substance which will increase the radio-sensitivity of cancer we shall have found the cure for cancer without radium. The most practical chapters on the actual methods of treatment are written by acknowledged experts, such as Mr. Stanford Cade and Mr. Arthur Evans, who have already recorded their methods elsewhere. Mr. Tudor Edwards describes the methods of attacking carcinoma of the oesophagus and other intrathoracic growths; Mr. Chubb deals with carcinoma of the larynx; Mr. Mullally with growths of the bladder and prostate, regions where the results have hitherto been very disappointing. Mr. Mullally is not yet able to record any striking advances. Lastly, it is clear that the Westminster Hospital team owe much to their technical adviser in the department of physics, Mr. Francis Rock Carling, who contributes a chapter on the applied physics of radium.

We look forward to future issues of similar volumes. What may not lie hidden under the title "Radium Practice, 1935"?

[1] *Westminster Hospital Reports*, Vol. XXI: *Radium Practice, 1929*. Edited by E. Rock Carling. London: H. K. Lewis and Co., Ltd. 1929. (Demy 8vo, pp. viii + 258; 12 figures. 7s. 6d. net.)

CRITERIA FOR THE CLASSIFICATION AND DIAGNOSIS OF HEART DISEASE.

In their campaign against heart disease the Heart Committee of the New York Heart Association published in 1923 a nomenclature for use in its various clinics. Feeling the need for uniform criteria for using the nomenclature, a committee, consisting of Drs. J. H. Bainton, R. L. Levy, W. C. Munly, and H. E. B. Pardee, was detailed to prepare such criteria, and this book[2] is the result of their efforts.

A complete diagnosis is intended to include a statement, not only of structural changes in the heart, but also concerning the cause of such changes, the disturbance of physiological function, and the state of the functional capacity of the organ. Four tables, therefore, contain a list of: (A) etiological factors; (B) anatomic changes; (C) physiological defects; (D) functional states; and a diagnosis would have a label from each of these. Other cases coming under observation are grouped under possible heart disease, or potential heart disease, with a label for Table A. Thus, for the classification of a case, one might have: (A) rheumatic (inactive); (B) mitral stenosis; (C) auricular fibrillation; (D) class 2*b* (that is, activity greatly limited). The authors then proceed in a systematic manner to deal in some detail with the criteria required in using the various terms supplied in the nomenclature, so as to ensure uniformity of diagnosis. Thus, in the chapter dealing with etiological criteria, there is a brief statement as to the various rheumatic manifestations; those that would justify the term rheumatic being used in the diagnosis are noted, and similarly with regard to syphilis, goitre, etc. Likewise, in the chapter on anatomical criteria are included notes on the more important physical signs or other tests that may be required to determine the cardiac lesions, while changes in rhythm are discussed under the physiological criteria. The functional classification follows the lines of the Heart Association. Class 1 are those with definite lesions but able to carry on ordinary physical activity without discomfort. Class 2 includes those unable to carry on without discomfort, and is divided into those in whom activity is slightly or greatly limited. Class 3 includes those with heart failure at rest.

As has been indicated, the book has been specially prepared to ensure accuracy in a big statistical inquiry, and we think it should serve a very useful purpose.

URINARY CALCULUS.

Stone and Calculous Disease of the Urinary Organs,[3] by J. Swift Joly, is a fascinating book which probably will become a classic in this department of medicine. The subject is very fully dealt with. It is introduced by a brief historical sketch, giving in outline the history of urinary lithiasis from the dawn of civilization down to the lithotomists of recent centuries. In the succeeding chapter the chemistry and physics of the composition and formation of calculi are discussed in a lucid and attractive manner, which renders it easy for the ordinary medical man to appreciate these difficult questions. Thereafter the general characteristics of calculi are considered and the etiology of stone discussed. The influence of diet, climate,

[2] *Criteria for the Classification and Diagnosis of Heart Disease*. By J. H. Bainton, M.D., R. L. Levy, M.D., W. C. Munly, M.D., *M.C.*, and H. E. B. Pardee, M.D. New York: Paul B. Hoeber, Inc. (*Cr.* 8vo, pp. xi × 91. 1.50 dollars net.)

[3] *Stone and Calculous Disease of the Urinary Organs*. By J. Swift Joly, M.D.Dub., L.R.C.S.*Eng*. London: W. Heinemann (Medical Books) Ltd. 1929. (7½ × 9¾, pp. xviii + 568; 189 figures, 4 plates. 45s. net.)

and infection are debated, and exact conclusions come to on the evidence produced.

The remainder of the volume, amounting to nearly 450 pages, is devoted to the clinical features of stone. The subject is considered regionally, beginning with renal calculus, the pathology being first of all considered, and afterwards the symptoms, differential diagnosis, and treatment. The use of radiography in renal lithiasis is very well illustrated by prints made from radiograms and outline drawings of these made from tracings. The medical treatment of renal calculus is dealt with from the standpoint of its prevention and the facilitation of its expulsion when once formed. The influence of diet on the production of stone is discussed in a very clear and rational manner. The various forms of operative treatment are fully described and well illustrated, and the accidents and complications occurring during operation and during convalescence are dealt with at length. Ureteral calculi are considered in a similar manner, but here a fuller account of the differential diagnosis might with advantage have been introduced. An entire chapter is devoted to calculous anuria, and this is one of the best features of the book. Lastly, vesical, prostatic, and urethral calculi are considered.

This work will not only prove invaluable to the specialist in urology, but it can also be recommended to any medical man who wishes to possess a book that he will read with ease and pleasure and learn much from. Each subject is fully debated, and when all the evidence available has been brought forward the author states his conclusions. His presentation is so clear and attractive that many readers will form the impression that if Mr. Swift Joly had embraced the law he would have been no less eminent as a pleader in the High Courts of Justice.

TREATMENT OF TUBERCULOSIS WITH SALTS OF GOLD.

DEALING with the treatment of tuberculosis by salts of the metals cerium, nickel, cobalt, and gold, Dr. J. V. LAMBEA, in his book on experimental tuberculosis,[4] draws general conclusions that are unfavourable to such methods. His experiments were performed on experimental animals of many varieties, chiefly rabbits and dogs, with the employment of normal animals as controls in addition to the use of animals infected with tuberculosis. In the case of cerium trichloride, the drug appeared to accelerate a fatal termination, and not to assist in the healing of tuberculous processes. With *bichloride of nickel*—a very poisonous substance causing diarrhoea, vomiting, and multiple haemorrhages in the control experimental animals—no effect was produced on the tuberculous lesions, and the infected animals died with lesions attributable to nickel poisoning in addition to those due to the tuberculosis. With binitrate of cobalt, a less toxic substance, the results were equally unsatisfactory; with cobalt, as with nickel, tuberculous animals were found to be less tolerant than normal animals, and the lesions due to these metallic poisons were found to be most marked in the neighbourhood of the tuberculous foci. With iodine, dissolved with potassium iodide in water and administered intravenously to dogs, Dr. Lambea had better results to record, but the treatment was a failure so far as the cure of experimental tuberculosis was concerned.

Nearly two-thirds of the book are given to the treatment of tuberculosis with compounds of gold, particularly the double chloride of gold and sodium, crysolgan, crysalbine, and sanocrysin. The author produces evidence for believing that all three compounds are violently toxic in the animal organism, producing haemorrhagic inflammatory lesions in many of the organs, including the lungs. He does not think it probable that such gold components are capable of destroying the tubercle bacilli in the infected tissues, whether in vitro or in vivo, so far as his own experiments have gone. A great many pages are devoted to the discussion of Moellgaard's arguments and findings in favour of the sanocrysin treatment of tuberculosis, but few of these are acceptable to Dr. Lambea, who produces a quantity of arguments based on his experimental researches to prove the dangers apparently inevitable when these gold compounds are used. The various reactions and the shock produced by sanocrysin in tuberculous patients, attributed by Moellgaard to the liberation of products of destruction of the tubercle bacilli, are referred by Dr. Lambea to simple metallic poisoning by the drug itself; he adds that sanocrysin has no specific action of any kind in tuberculosis, whether on the bacilli themselves or on the tuberculous foci, and that the organic lesions it produces are almost identical with those produced by salts of nickel or cobalt. So far as his own observations on patients treated with sanocrysin go, he concludes that many of them would have done better without the treatment, while others were improved by it.

Dr. Lambea's book is clearly written and full of facts and observations recorded in the course of his numerous animal experiments; in addition, it is illustrated by a number of photographic reproductions and coloured photomicrographs. Lack of space prevents the mention of any but a few of his clinical and pathological records; his book should be consulted by all medical men who have to do with the treatment of tuberculosis with salts of gold.

MASTERS OF PHYSIC.

IN 1911 *The Corner of Harley Street* appeared anonymously and, like the unauthorized editions of Sir Thomas Browne's *Religio Medici*, it aroused much admiring curiosity; in the second edition the authorship was admitted by Dr. H. H. BASHFORD, who has now provided the increasing number of those interested in medical history with essays on eleven great figures in medicine, under the title of *The Harley Street Calendar*.[5] This might suggest an account of those who have had this professional address—an attractive subject once brought before the Abernethian Society of St. Bartholomew's Hospital by Sir Archibald Garrod—and a captious critic might object that it is unkind to recall the *Newgate Calendar, or Malefactor's Bloody Register* (1775), and that none of these fathers of medicine actually dwelt in a street so famous that it here and now appears to stand for the whole art and science of physic. In these charmingly written sketches the progress of medicine in Britain is outlined by accounts of those who are specially associated with its milestones. Some of them, such as Lister, Edward Jenner, John Hunter, and Harvey, have influenced the whole world, whereas the first three names, Gilbert the Englishman, John of Gaddesden, and Thomas Linacre, are mainly of historical interest. The subject of the last essay is the life-pilgrimage of William Osler, in whose presence "neither envy nor malice could live," whose "textbook was the first to embrace and reissue in concise form the enormous changes wrought in medicine by the discovery of microbic infection," and of whom it is said that he had shown "more than any man of his age, perhaps, that the life of the spirit has no borders." The contrasting features shown by Harvey, who was one of the few who "conquered envy," and Thomas Sydenham, the prince of practical physicians, are set out, and the activities of Hans Sloane (like John Fothergill, a seventh son) as a botanist, a court physician, founder of the British Museum, and squire of Chelsea are pleasantly told. Dr. Bashford's essays are often skilfully grouped; thus that on James Y. Simpson, which summarizes the history of anaesthesia, immediately precedes that on Lister, and, like the others, is a masterly sketch of a great personality.

DENTAL INFECTION AND GENERAL DISEASE.

IN a small publication entitled *Dental Infection and Systemic Disease*[6] Dr. RUSSELL L. HADEN records his researches in dental infection. The extensive character of his work, both clinical and experimental, and the moderation with which the author expresses his views, will ensure a careful examination of the evidence here brought

[5] *The Harley Street Calendar.* By H. H. Bashford. London: Constable and Co., Ltd. 1929. (Cr. 8vo, pp. 272. 7s. 6d. net.)

[6] *Dental Infection and Systemic Disease.* By Russell L. Haden, M.D. Philadelphia: Lea and Febiger. (5½ × 8½, pp. x + 165; 63 figures. With a foreword by Dr. Edward Rosenow. 2.25 dollars net.)

forward by all interested in the subject. There is no doubt in his mind of the danger of dental infection, and in enforcing his views the author makes frequent use of statistics—and as he deals in hundreds or thousands of records he is fully justified in doing so—and always figures speak loudly against the tooth. Pulpless teeth with negative radiographic findings were found to show almost as high a percentage of bacterial infection as pulpless teeth with positive radiographic findings. The author supports Rosenow in his theory of elective localization, but admits the coexistence of other lesions in the experimental animal. In the course of his summing-up Dr. Haden says, "There is no convincing proof that periapical infection can be cured by root-canal treatment. Areas of rarefied bone at the apices of teeth resulting from infection may partly or completely fill in following treatment with different sterilizing agents. This does not prove that such areas have become bacteria-free, since it is well known that bone regeneration often takes place in the presence of active infection. No satisfactory bacteriological studies have been made after treatment of such areas to prove they are really sterile. Few competent dental clinicians believe that any attempt should be made to treat such teeth." This is a reasoned statement and challenge, and is characteristic of the book. In the author's hands glucose brain agar and glucose brain broth have proved a valuable means of providing a graduated oxygen tension.

The book is a valuable contribution to medical and dental literature, and the author has done a real service to medical history in rescuing from oblivion the names of those who, a hundred years ago, first drew attention to dental infection.

NOTES ON BOOKS.

THE fourth edition of *The Nervous Child*,[7] by Dr. HECTOR CHARLES CAMERON, of which the first appeared in 1919 and the third in 1924, has been enriched by the addition of a chapter on the underlying disturbances of metabolism in the nervous child. In this the author emphasizes the importance of study of the biochemical changes occurring in nervous children, and particularly an examination of the blood sugar curve, and recommends appropriate diets in children suffering from acidosis, for whom glucose in the form of a drink flavoured with fruit juice and the daily prescription of a small dose of alkali are specially recommended.

The title of the booklet *What You Should Know About Heart Disease*[8] indicates that it is intended for the lay reader. In it Dr. HAROLD PARDEE gives an elementary, but at the same time reasoned, description of the function of the heart, the diseases which affect it, the lesions produced, and their effect on function. A large portion is taken up with various aspects of treatment. Medicines are discussed, not as regards dosage, but as to their mode of action. To a limited number of patients with heart disease the book may be of value, but one doubts the wisdom of a familiarity with such terms as heart-block, dropped beats, and auricular fibrillation.

The fifth edition has now been published of *Physiology of the Central Nervous System and Special Senses*,[9] by N. J. VAZIFDAR, of which the third edition was noticed in our issue of June 26th, 1920. In revising this compilation the author has not departed from the original scope and style of the book, and, accordingly, only such new matter has been added as is likely to prove useful to students preparing for their intermediate M.B. examination.

We have received eleven more issues of the German series of booklets[10] intended for the general practitioner, to which we drew attention last year (*Journal*, October 27th, 1928, p. 752). The subjects and authors are as follows: No. 7, treatment of dislocations, by Professor Carl Ewald; No. 8, treatment of fracture by simple methods, by the same author; No. 9, jaundice, by Dr. Alfred Luger; No. 10, disturbances in the frequency and rhythm of the pulse, by Professor Edmund Maliwa; No. 11, menstruation and its disturbances, by Professor Josef Novak; No. 12, intestinal diseases, by Dr. Walter Zweig; No. 13, infant feeding, by Professor August Reuss; No. 14, comatose conditions, by Dr. Viktor Kollert; No. 15, diathermy, hot air, and the mercury lamp, by Dr. Paul Liebesny; No. 16, introduction to orthopaedics, by Dr. Guido Engelmann; and No. 17, disturbance of speech and voice, by Professor Emil Fröschels. The present instalment, like the preceding issues in the series, is characterized by the clear, concise, and practical manner with which each subject is treated. The booklet on intestinal diseases, which may be taken as an example, contains introductory matter dealing with the anatomy, physiology, and pathology of the intestine, as well as the various methods of examination of the patient, followed by a consideration of intestinal affections, with their dietetic, pharmaceutical, and physical treatment.

Condensation is a difficult art, and is usually achieved at the expense of clarity. Miss LOUISE HENDERSON, of the central branch of the Y.W.C.A. of New York, has tried to condense into a small textbook all the knowledge required by trained attendants for use in practical home nursing. The result is quite a useful little book, *Practical Nursing*,[11] with several illustrations of the way to move and arrange patients in bed, and of methods of bandaging, which help to elucidate the text.

Of the making of books on crime and criminals there is no end. Dr. A. SALUSBURY MACNALTY has converted a dozen *causes célèbres* into more or less veracious stories, under the title *A Book of Crimes*.[12] In his preface he admits that the poetic justice awarded in his account of the case to the Abbé de Ganges is unauthenticated, and that this monster of iniquity is said to have died a natural death in Holland soon after his marriage. However, the stories make agreeable reading wherewith to while away an hour or two, and the poisoning cases have an element of medical interest.

Within the compass of some ninety pages Mr. J. S. BAINBRIDGE has written a most attractive and useful little book[13]—mainly intended for the housewife—on the commoner pests encountered in the household and simple methods for their destruction. The pests—insects, mites, rodents, and moulds—are treated in alphabetical order in separate chapters. Each chapter is short, illustrated, and easily readable, and is mostly devoted to a consideration of the life-history of the particular pest and methods to be adopted for its control. The information is simply but accurately given, and the methods recommended are cheap and safe; so far as possible they are illustrated by line drawings of a very helpful character. The book is sure to find a wide and appreciative public, and can be safely placed in the hands of laymen, where it should do much to help to combat some of the minor horrors of the household.

PREPARATIONS AND APPLIANCES.

ANZYPAN.

"ANZYPAN" (H. R. Napp Limited) is a preparation for the oral administration of gastric and intestinal enzymes. The tablets have an external coating soluble in gastric juice; inside this is a layer of dried gastric ferments (pepsin, diastase); whilst the core is composed of a mixture of the intestinal ferments (gall, trypsin, lipase) covered with a coating that is soluble in alkaline medium in the intestine only. The construction of these tablets is very ingenious, and the makers report that clinical tests show that cases of dyspepsia due to enzyme deficiency are benefited by this preparation.

CITRAGAN.

"Citragan" is a silver compound elaborated in Denmark for the local treatment of gonorrhoea. The compound is silver-sodium citrate, and the special advantages claimed for it are that it yields a considerable content of ionized silver, and yet does not produce irritation of the urethral mucous membrane. Very favourable results are reported from clinical trials. The product is prepared for urethral injection in liquid and in bougie form. The liquid contains 0.27 mg. silver per c.cm., whilst the bougies contain 1.27 mg. silver per c.cm. Messrs. Oppenheimer, Son and Co., Ltd., are the sole distributing agents for the British Empire.

THE BIOCHEMISTRY OF NERVE TISSUE.

A Survey of the Position.

BY

ERIC G. HOLMES, M.B., B.Ch.,

ASSISTANT TO THE DOWNING PROFESSOR OF MEDICINE AND DEMONSTRATOR OF PHARMACOLOGY IN THE UNIVERSITY OF CAMBRIDGE.

In a recent article[1] Dr. W. F. Menzies spoke of the need for a biochemical approach to some of the problems of mental disease; it was evident that he had in mind a real analysis of the function of nerve tissue, on biochemical lines, and not a mere search for "tests" of a chemical nature, that might prove of assistance to diagnosis. An understanding of the chemical dynamics involved in the function of the nervous system would be of very obvious assistance, not only to the psychiatrist, but also to the pharmacologist; indeed, the latter might turn to useful account knowledge which was of too rudimentary a nature to be of very great use to the former.

An increasing amount of work on the biochemistry of nerve tissue is being done, and perhaps it is worth while to review briefly the present position. Such a review will make it clear that the subject is still in its infancy; and the feeling on the part of the public that the laboratory worker should "produce rabbits out of his hat," to which Dr. Menzies refers, and in which, perhaps, the clinician is at times tempted to share, may prove rather inhibitory to workers who are well aware that no immediate "practical" results are likely to crown their efforts. Nevertheless, until the preliminary spade work is accomplished, and some of the fundamental principles are laid bare, it is hardly to be expected that the more intricate phases of the problem can be dealt with successfully.

The problem that naturally first presents itself is that of conduction in the nerve fibre. Since the last century many workers have investigated the electrical changes that accompany nerve activity and their relationship to conduction. Work of this type forms the basis of the current theory of nerve conduction (Lillie[2]). The classical researches of Keith Lucas and of Adrian, to mention only workers in our own country, are almost too well known to require mention. The rapid development of electricity, and in particular of the thermionic valve, has given a great impetus to work of this kind. In America, Bishop, Erlanger, and Gasser have used a combination of a valve amplifier and a cathode ray oscillograph; Forbes has combined the amplifier and the string galvanometer; and in this country Adrian and Matthews have used valves and the capillary electrometer, and an oscillograph, respectively. By such means these workers have elaborated techniques which allow of observations of a delicacy and an accuracy hitherto quite unattainable. The importance of these researches from the point of view of the analysis of nervous activity cannot be overrated. Undoubtedly they represent one aspect of biochemical phenomena, just as surely as do the measurements of the chemist, but we have not yet the knowledge required to correlate them with those measurements.

From the more obviously chemical point of view, perhaps the most fundamental, though by no means the earliest, observation was that of Downing, Gerard, and Hill,[3] who showed that peripheral nerve gives out a minute but measurable amount of heat during rest, and that this heat is increased during stimulation. The heat associated with a single impulse in a frog's nerve at 15° is in the neighbourhood of one-millionth of a calorie per gram of nerve. Like active muscle, active nerve gives out heat in two stages—there is an "initial" and a "recovery" phase; but whereas, in the case of muscle, the ratio between the magnitudes of these two phases is about 1 to 1, in nerve it is about 1 to 9; moreover, in muscle the two phases can be separated, since the "recovery" phase is abolished in the absence of oxygen; but in the case of nerve no such separation is possible; in nitrogen both phases fail together. These facts indicate that the chemical events which underlie the evolution of heat must be different in nature in the case of the two tissues.

Several workers have investigated the gaseous metabolism of nerves. The earliest work was that of Tashiro,[4] who estimated the carbon dioxide given off by frog nerve, both during rest and activity. Schwiehi Niwe,[5] using Tashiro's method, showed that this evolution of CO_2 was diminished by cocaine. The accuracy of Tashiro's method has been seriously questioned, and later workers, Parker[6] and Adam,[7] have attacked the problem with better methods. They have confirmed the qualitative aspect of Tashiro's work, in that they also observe an evolution of CO_2 at rest, which is increased during stimulation, though they have shown that, qualitatively, his values were inaccurate.

Of very great interest is the work on the oxygen absorption of nerve tissue and its relation to the evolution of CO_2 and of heat. Gerard[8] observed the oxygen consumption of frog nerve, and found values which agreed very well with those previously obtained for heat production, on the assumption that, both during rest and activity, the source of energy was the oxidation of the ordinary food materials (carbohydrate, protein, or fat). Fenn's[9] values are in substantial agreement with those of Gerard, and the results of both workers have recently been confirmed, in the main, by Meyerhof.[10] These workers all employed the nerves of cold-blooded animals. Observations of mammalian (rabbit) nerves have, however, been carried out by Gerard[11] and Sherif.[12] The results of these two workers show close agreement. Sherif's observations cover both normal nerves and nerves which are exposed to the action of certain drugs.

Taken together, these observations establish the very fundamental point that in the nerve, no less than in tissues such as muscle, we have to do with energy-yielding processes which can be interpreted in the familiar terms of heat, energy, and chemical change, and which therefore can be attacked by the biochemist with hope of ultimate success.

It is natural to seek a clue to the nature of the foodstuffs oxidized by examining the respiratory quotient. Unfortunately, however, the data on this point are still inconclusive. The problem of making simultaneous accurate measurements of oxygen and carbon dioxide on a minute scale is beset with technical difficulties; in point of fact, there is not, as yet, complete agreement between the three workers (Gerard,[13] Fenn,[14] and Meyerhof[15]) on the question. All, however, agree that during activity there is a tendency for the respiratory quotient to rise to, or above, unity—a finding that would naturally be interpreted in the sense that, whatever foodstuffs may be used during rest, activity entails the burning of carbohydrate.

Attempts have been made to observe directly the materials oxidized. Hirschberg and Winterstein's[16] results seem to show that there is a diminution of carbohydrate, protein, and fat in frog nerve during both rest and activity.

Gerard and Meyerhof[17] investigated the formation of lactic acid by frog nerve. They used, for the most part, manometric methods, and concluded that there was a production of lactic acid during survival of the nerve in nitrogen, which was not increased by stimulation. They found reason to believe that carbohydrate furnished the source of this lactic acid production. In oxygen there was no evolution of lactic acid; on the other hand, they could find no unequivocal evidence of the removal of this substance, which, on analogy with the behaviour of muscle, would be expected to take place. Holmes and Gerard[18] have approached the same problem. They employed rabbit nerves, a course which complicated the immediate experimental procedure, since it entailed working at 37°, but which very greatly facilitated the chemical investigations, since adequate amount of tissue could be obtained—a very difficult problem when frog nerves are used. They verified the fact that nerve produced lactic acid when kept in nitrogen, and were able to show a corresponding fall of carbohydrate, to which glycogen and "free sugar" contributed about equally. They showed definitely that there was no production of lactic acid in oxygen, but that there was, on the other hand, a disappearance of carbohydrate. They do not assume that this carbohydrate is oxidized, though they point out that, if it were, it would account for about half of the observed oxygen utilization.

They were able to establish definitely that there is no oxidative removal of lactic acid, a point which serves

quite sharply to differentiate the chemical behaviour of nerve from that of muscle. Finally, they found that these processes, definite enough in the resting nerve, are quite unaltered by stimulation. The importance of this finding is considerable, for clearly it means that we must look elsewhere for the source which provides the energy for the nervous impulse; it is, indeed, almost refreshing to meet a tissue which has apparently rejected glycogen and glucose as a source of energy supply!

Tashiro[19] first showed that peripheral nerve produced ammonia, and that ammonia production was increased by stimulation. These results have been confirmed by Winterstein[20] and by Gerard and Meyerhof.[17] These observations may be related to the breakdown of adenylic acid (Embden[21]). Thudichum[22] long ago described the presence of hypoxanthine in brain, and its presence has recently been confirmed by Holmes and Holmes, who isolated it as the silver nitrate (unpublished). They also observed that a pentose was present in brain tissue.[23] Adenylic acid contains a pentose group, adenine and phosphoric acid; and adenine, by oxidative de-amination, would yield hypoxanthine.

This brief survey indicates that at least a beginning has been made in unravelling the chemical factors upon which the propagation of the nervous impulse depends. If, so far, what has been done amounts only to a few scratches on the surface of the problem, at least we possess the very important knowledge that the nervous impulse is accompanied by the evolution of heat and the consumption of oxygen, and that its source of energy is different from that of muscle.

If much remains to be done with regard to the problems of conduction, still more difficult are the tasks presented by the central mechanisms, those of the brain itself. It would seem that there is a fundamental difference between the chemical events occurring in peripheral nerve and those taking place in the brain, for this reason: the oxygen consumption of peripheral nerve, both in rest and activity, is extremely small—of the order of 300 c.mm. per gram per *hour* for mammalian nerve at rest, and of perhaps 1,000 c.mm. per gram per *hour* during activity. It is doubtful whether the oxygen consumption of normal, unanaesthetized brain has ever been measured with even approximate accuracy, but the oxygen consumption of anaesthetized brain is of the order of 30 to 50 c.mm. per gram per *minute*—and anaesthetics are known to inhibit oxidation processes to a very marked degree. Thus *anaesthetized* brain consumes, at the very least, six times as much oxygen as unanaesthetized resting nerve (Alexander and Cserna,[23] Hou,[24] Hou and Siguira,[25] Schmidt[26]). Warburg, Posener, and Negelein[27] have shown that brain tissue produces lactic acid very rapidly *in vitro* in the presence of added glucose. Holmes and Holmes[28 29 30] confirmed these findings, and showed, further, that the carbohydrate reserve of brain is very poor; during anaerobic survival very little extra lactic acid is produced unless glucose is added to the preparation. Following up this observation, they produced evidence to show that during life brain is dependent for its lactic acid precursor upon sugar supplied to it by the blood stream, since the amount of lactic acid which can be found after death depends on the level of the blood sugar at the time of killing. In insulin hypoglycaemia the brain lactic acid content may be less than half its normal value; if the animal is killed during hyperglycaemia, however produced, the value may be increased by as much as 200 per cent., depending again upon the precise blood-sugar level. Now hypoglycaemia of a sufficiently severe degree is accompanied by convulsions. On the other hand, one of the causes of hyperglycaemia is the administration of anaesthetics such as ether, chloroform, or urethane. A low brain lactic acid value may therefore accompany increased activity, a high value may coexist with anaesthesia. It is difficult to interpret these findings if it is assumed that lactic acid represents some phase in the chemical process accompanying active impulse conduction, but the difficulty is less acute now we know that it is not this lactic acid mechanism which is directly concerned, at least in the propagation of the impulse. It has been shown that lactic acid is not oxidized by peripheral nerve; brain tissue, however, oxidizes it very readily (Holmes and Holmes[24]). It seems very likely, therefore, that this power of oxidation is inherent in the nerve cell, as opposed to the nerve fibre, and it is tempting to speculate whether the oxidative removal of lactic acid may not be connected with the passage of impulses over the synapse.

Ashford and Holmes[31] have investigated the phosphorus metabolism of brain from the point of view of lactic acid production. They find that, so far as the production of lactic acid from glucose is concerned, phosphorus appears to play *no part*; *on the other hand*, the formation of lactic acid from glycogen seems to involve the production of hexose phosphate as an intermediate stage. These investigations bear, perhaps, more on the general questions of carbohydrate metabolism than on the particular problems connected with the brain. They serve, however, to underline the difference between the carbohydrate mechanisms of brain and those of muscle tissue. Incidentally, these experiments have again emphasized the very much more important part played by glucose than by glycogen in the production of lactic acid by brain. Attention has been drawn to this point in earlier papers.[28 29] There seems to be no doubt at all that an abundant supply of glucose is absolutely necessary for normal brain function, and that, since little carbohydrate can be stored, the supply must be carried by the blood stream; that apparently neither glucose nor lactic acid provides the energy liberated during impulse conduction in the fibre renders the question all the more intriguing.

ROYAL MEDICAL BENEVOLENT FUND.

At a recent meeting of the committee of the Royal Medical Benevolent Fund £610 was voted in grants to thirty-five applicants. The following are short notes on two of the cases helped.

A medical man, aged 76, has been bedridden for two years following a stroke; he is now quite childish and unable to look after himself. His two sisters are dependent on him; one is bedridden with cancer; the other, aged about 60, is very frail, and alone looks after these two invalids. She cannot afford a servant or a nurse, and all the household work and the nursing falls upon her. Their income, about £110 a year, is derived from letting rooms in the house. Voted £40.

Daughter, aged 59, of M.D., is crippled with arthritis and unable to use her hands and feet. Her knees are quite fixed, as well as her left arm. She shares a bungalow with an annuitant of this Fund, who is 87 years of age; it is therefore necessary for these two ladies to pay someone to look after them. The grantee's income, £60, is from a sister. The annuitant's income from this Fund and other charities is £130, making a total of £190. Rent amounts to £90, and wages of attendant £39. This leaves £61 for the maintenance of the two ladies. Voted £26 to the grantee, in addition to £20 to the annuitant.

The committee is very restricted in the grants which it is able to make owing to the limited funds available for distribution. Subscriptions and donations are very urgently needed before the end of this year, and should be sent to the Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, Cavendish Square, London, W.1.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 58, Great Marlborough Street, W.1.

MENTAL HEALTH AND SOCIAL PROBLEMS.

CONFERENCE IN LONDON.

The National Council for Mental Hygiene and the Tavistock Square Clinic united in organizing a conference on mental health, which was held at the Central Hall, Westminster, on October 30th and the three following days. About eighty organizations, mostly bodies concerned with educational and social welfare work, and including the British Medical Association, co-operated in the conference, whose eight sessions resulted in an interesting series of discussions, the social implications of the subject, especially as related to the child, being very well covered. Representatives were present from the German and the Belgian Leagues for Mental Hygiene, and messages were read from corresponding bodies in Italy, Switzerland, and Russia. The Minister of Health, in sending his good wishes for the conference, stated that the Government appreciated the need for increasing the facilities for early mental treatment, and hoped, if the exigencies of parliamentary time permitted, to introduce legislation for this purpose.

The Beginnings of Mental Disorder.

The inaugural meeting was presided over by Viscount Brentford, supported by the chairmen of the two convening organizations—namely, Sir Maurice Craig and Dr. H. B. Brackenbury. Lord Brentford expressed his wish to see a chair of mental hygiene in every university and medical school.

Sir Maurice Craig remarked on the misfortune that in the past, and to no small extent to-day, mental disturbance and insanity were regarded as one and the same thing, whereas in fact there were many degrees of disturbance of mind, and only the most serious were to be denoted as insanity. The very way in which people shrank from using the word "mental" was a sign of the fear with which this subject was regarded, a fear which would be largely dispelled by a fuller knowledge of the constitution and working of the mind. The greater the public enlightenment on this subject, the less would be the embarrassment in speaking of or dealing with it, and the less likely would people be to tolerate artificial and unscientific restrictions. The ill-informed outlook of the past, said Sir Maurice Craig, had increased the suffering of the patient, and had discouraged the study of his disease. Progress in this realm was slow; it was now nearly four years since the Royal Commission on Lunacy and Mental Disorder reported, and yet nothing had been done. It was important, he continued, to cease to think in terms of mind and body as separate and independent entities. Minor disturbances of the mind might be brought about in endless ways and by a variety of stresses, some of them physiological, and including child-bearing in the case of a physically enfeebled and emotionally unstable woman. Mental disturbance must not be regarded as a "bolt from the blue." It was commonly a slow and progressive failure, the early stages of which were very frequently overlooked or misunderstood. To prevent such oversight and misunderstanding the National Council for Mental Hygiene had come into existence, though the magnitude and value of its work had not yet caught the popular imagination.

Dr. Letitia Fairfield spoke on the application of mental hygiene in child guidance. The idea of mental hygiene, she said, was only superficially novel; in reality it was merely an expansion of well-tried principles worked out in other spheres. Modern criminology and modern psychology, starting from wholly different aspects, had united in demonstrating the importance of childish habit-formation and impressions on adult behaviour. The origin of the trouble of the confirmed criminal on the one hand and of the chronic neuropath on the other was likely to be found in a misunderstood childhood. It was mainly in America that the intensive study of the delinquent and difficult child had been worked out, but the methods were available for international application. Successful schemes of child guidance would always be found to depend on certain simple factors, such as a thorough examination of the child and his environment for a diagnosis of the problem; co-operation with parents, teachers, and other persons in authority over the child, and constructive plans for strengthening character and developing good habits. Without careful investigation it was impossible to say whether the source of the trouble was physical defect, an overlooked deficiency in intelligence, bad example in the home, or emotional stress in the environment. The causes were rarely single; hence the need for thorough examination in each case. Dr. Fairfield added that the chief danger which this new movement had to fight was the enthusiasm of child-lovers, who thought it all sounded "so simple." American experience of child guidance clinics was overwhelming that the work was extremely difficult, and needed highly trained experts with a background of exact scientific knowledge of the psychology of mental disorders.

Mr. L. G. Brock and Sir Frederick Willis, the present and past chairmen of the Board of Control, and the Rev. Canon T. W. Pym were among other speakers at the inaugural meeting. The last-named expressed gratitude to the Tavistock Square Clinic, from which, he said, he had obtained useful assistance on behalf of people whose trouble was essentially as much a matter of mental ill health as of moral or spiritual failure.

Sex Education.

One of the sessions of the conference was devoted to a frank discussion of sex education. The subject was opened by Mr. W. H. Fyfe, headmaster of Christ's Hospital, who expressed the view that any boy the development of whose sexual functions had become disturbed was the victim to some extent of three causes: ignorance, a wrong kind of righteousness, and the attitude towards sex which was mirrored from the stage, the "pictures," and certain newspapers. It was futile for the schoolmaster generally to set about giving information, because he never knew the right time at which to give it. Any kind of formal lecture given mechanically was almost certain to do more harm than good. The only recourse was a word in season; but how was the schoolmaster to find the season? Any kind of disquisition, psychological or sociological, would leave the boy of fifteen just as ignorant as before, and probably still more pruriently curious. The persons who had the best, perhaps the only, chance of discovering the right season were the parents and guardians of the child. The manner as well as the season was important. The lads, he thought, should be taught to look forward to a happy marriage, which linked romance to health, and encouraged the view that sex was the root of the finest flowering of human nature. The house master should encourage the boys to regard their sexual functions in the same light as their other physiological functions—that is to say, to disregard them normally, and to seek proper advice in any abnormality or disturbance.

Miss Geraldine Coster, headmistress of Wychwood School, Oxford, spoke similarly with regard to girls. The child, she said, was never shocked by sex information given at the time the child wanted it; the child was shocked when information was given at the wrong time. She was rather sceptical of the value of nature study so often advocated. The child was quite capable of understanding all about a litter of guinea-pigs and of still believing that angels brought babies in at the window. She criticized also the pamphlets on the subject so widely distributed; they were so desperately sentimental. She thought it best to give instruction to children singly or perhaps, in the case of very young children, to a couple of friends. It should be complete as far as it went. In discussing birth, the method of actual childbirth should be clearly dealt with; otherwise various fantasies would arise. "Be matter-of-fact; eschew sentiment, and do not talk too much about beauty and holiness; those things can be conveyed without talking about them." The school itself could inculcate a hatred of subterfuge and set a high ideal of service, citizenship, and personal integrity.

Dr. H. Crichton Miller, honorary director of the Tavistock Square Clinic, said that many adults, unconsciously, did not want the children to grow up. That was a well-known genetic reaction commonly seen among herd animals. Especially in the department of sex the parent wanted to keep the child in the dark. It was natural that parents should wish to safeguard the happiness of the young people entrusted to them in relation to their sex life, but the

parent-fixated child was not the strongest character. It was a question what kind of adult was qualified to "put across" to the child the right feeling towards sex. Certainly the disillusioned and frustrated had better keep their tragedy to themselves; it was not the bitter or cynical who would help young people to find in the complete fruition of sex life the reward of continence, partial or complete. Many adults were in such a muddle themselves, in such a state of confusion, resistance, conflict, and self-recrimination, that they were helpless in the presence of a child's innocent question. Any psychiatrist of experience could bear that out with scores of instances. Much depended upon the right way of approach. When a child in innocence had found satisfaction in masturbation it was not right to exclaim at the act as "horrid"; the adult ought not to project his own moral and sentimental feelings into that which the child could not understand. The child had to be asked to exercise self-restraint, as children should be asked to accept external discipline generally, on grounds as far as possible comprehensible to himself. The demand for self-restraint should be based on something positive, not negative, and should be made by those who could present to the young person's mind the rewards of continence in the future fruition of sex, not as a thing enveloped in incomprehensible taboos, but as a sacramental experience.

Mental Hygiene in Social and Public Health Work.

Sir George Newman, chief medical officer of the Ministry of Health and of the Board of Education, presided over a session at which the place of mental hygiene in social and public health work was discussed, and brought to the conference the good wishes and interest and sympathy of the two departments of State he represented. He sketched the dimensions of the problem of mental abnormality: 140,000 lunatics, and 300,000 mental defectives, though, to be sure, these added together accounted only for 1 per cent. of the population. But, in addition, there were a large number of backward or retarded persons, reckoned possibly at between 5 and 15 per cent. of the people of the country. The burden was a heavy one, though not nearly so heavy as the burden of physical disease, and it was partly explained by the enormous advances in public health, whereby every year about 40,000 infants were surviving who would have perished had the infant mortality rate of thirty years ago continued. Among those who were saved must be many who would presently show signs of mental defect. "Someone may ask, 'Why don't you let them die?' To that I have no rejoinder, except that it is my business, charged by you, and by the Hippocratic oath to which I am sworn as a medical man, to save every life every time that I can, no matter whether that life is going to develop into strong and healthy citizenship or is going to end on the gallows."

Dr. H. P. Newsholme, medical officer of health for Birmingham, read a closely reasoned analytical paper on the principles underlying mental health, and indicated ways in which health visitors and social workers could give instruction and make adjustments so as to prevent breakdowns. Miss Hester Viney of the College of Nursing spoke of the role of the public health nurse, and the opportunities afforded to her for effective educational work; and Miss E. M. Lawrence, the chief social worker of the Child Guidance Clinic, followed with a paper on the usefulness of the social worker in dealing with behaviour problems in the early stage.

The Problem Child.

The problem child—or perhaps more correctly the problem parent—was the topic of another group discussion, presided over by Dr. R. H. Crowley, senior medical officer, Board of Education. The first speaker, Miss Neville, a psychologist of the Home and School Council, suggested that the problem child was more frequently the brilliant child than the dull child. The brilliant child was a misfit even more than the dull. He had endowments above the children of his years, and yet he was compelled more or less to go at their pace. Her remedy, in the shape of special classes for brilliant children, called forth a criticism from a teacher in the audience, who pointed out that, after all, in life those with exceptional mental parts had to accommodate themselves to all sorts of persons, most of whom were inferior to them in gifts, and that the school, which is a preparation for life, might well begin the necessary social adaptation.

The educationists present also fell foul of the second speaker, Dr. E. A. Hamilton-Pearson of the Tavistock Square Clinic, who complained of education that it tended to confine, during the years that the mind was capable of profiting from the widest variety of experience, the intelligence of the child to a strict monotony of almost unvarying intellectual routine. Education, he said also, had created the problem child by its adherence to a purely intellectual ideal, and its apparent assumption that all minds were fundamentally similar, if not in quality at least in form, and able to compass similar instruction. There was no one type of mind, but there were several types, demonstrably different in their main lines of interest, their aptitudes, and their intellectual capacity. The educational system, however, found many defenders among the audience.

The subject of "The child and the parent" was treated, among others, by D. Helen Boyle, a member of the Child Guidance Council, who had some refreshing things to say about it. Dr. Boyle spoke of the danger of too great perfection of bringing up, too much regularity, care, and notice. "It does the healthy child no harm to overeat itself on cream buns and be sick. It learns more about satiety and the ways of its body than any other sort of teaching can give. No longer does it need to exert will-power to refrain from overeating; it feels nauseated by the thought, and it recognizes the first symptoms." Dr. Boyle did not want anyone to think that the child was better for unkindness, but there was perhaps at times an unreality of atmosphere which was a poor preparation for adjustment to life. Let a child be always fed at the right moment, on the right things, wake at the right moment, sleep in a darkened room in a tomb-like silence, and take the right amount of exercise, and at the right time, and in after life he would be a quite unadaptable person, fidgeting if his dinner was a few minutes late, and sleepless in an unaccustomed environment. The secret of life, a philosopher had said, was to remember, "Of nothing too much!" That was pre-eminently true, in Dr. Boyle's opinion, of bringing up children.

The delinquent child as a problem in mental hygiene was the subject of an excellent address by Mr. W. Clarke Hall, the metropolitan magistrate at Old Street Police Court. He traced the gradual improvement in the public attitude towards the delinquent, from the almost unbelievably harsh sentence of former times, to the present gentler age, when the scales of justice were more evenly balanced, though even yet the underlying circumstances which brought about the delinquency were not understood. There could be no true justice, said Mr. Clarke Hall, without knowledge of the circumstances of environment and heredity, and a complete knowledge of such things was still unprovided for in English law. He considered the juvenile court from the sociological point of view to be the most important tribunal in the country. Most habitual criminals began their career at an early age—50 per cent. of them before they were 21. The first and principal of several recommendations which he made for dealing with delinquency was that juvenile courts should be rendered really efficient.

It is impossible even to mention some of the other excellent speeches and discussions in the four-day conference, but a word should be said about the session, over which Sir Charles Wakefield presided, on the personal equation in industry. Dr. Millais Culpin, research worker for the Industrial Fatigue Research Board, gave a very interesting account of a study of the mental and nervous reactions in 1,500 workers of all ages and classes, pointing out how symptoms might be exacerbated by working conditions, and what a close connexion existed between nervousness and social maladaptation. It was encouraging to hear Dr. Culpin say that he had never seen a breakdown due to overwork pure and simple, though he had seen the "fussy" person break down under stress of work. The 25 per cent. of nervous individuals might also feel happy in hearing that some of the world's best work had been done by nervous people.

British Medical Journal.

SATURDAY, NOVEMBER 9TH, 1929.

THE ASTHMA PROBLEM.

FROM its striking clinical features asthma has long been known; the first book on the subject in English was written as far back as 1698 by a sufferer, Sir John Floyer (1649–1734) of Lichfield, who, according to his one-time patient and fellow townsman Samuel Johnson, "panted on to ninety," although as a matter of actual history his earthly pilgrimage fell short by five years of fourscore years and ten. Asthma has also been described by other medical sufferers, such as Hyde Salter (1859), whose account may be still read with advantage, Trousseau (1866), W. E. Steavenson (1879), Arthur F. Hurst (1921), and J. R. Charles (1925), and during the present century it has been the subject of much work and many hypotheses. That the mechanism of the asthmatic crisis is contraction of the bronchial muscles as the result of vagal stimulation rather than swelling of the bronchial mucous membrane was established in 1902 by the experimental observations of Brodie and Dixon. A full summary of their original report was given, at the request of several correspondents, in our issue of July 13th last (p. 68). The suggestion in 1910, by S. J. Meltzer of New York, that asthma is anaphylactic in origin was followed by an enormous amount of work on its relation to other idiosyncrasies—or toxic idiopathies, to use Dr. John Freeman's happy label—and on skin tests as a means of detecting the foreign protein responsible for the reaction, and this work in turn was followed by the widespread practice of measures of desensitization by protein therapy. The influence of heredity on the occurrence of asthma and other forms of hypersensitiveness has been proved, and this has coincided with the recent revival of belief in the constitutional factors of disease. The importance of the psychological factor and of auto-suggestion in exciting attacks of asthma has been rightly insisted upon. That there are a large number of sufferers is shown by the estimate, made some years ago, that in North America 3.5 per cent. of the population is affected, and by the more recent estimate that the number of persons affected in this country amounts to 200,000.

It is not surprising that the subject of asthma has often been discussed—in fact, during the last twenty years no fewer than six times in different Sections at the Annual Meetings of the British Medical Association. In the discussion on this subject in the Medical Section at the recent Manchester meeting the opening paper (printed this week at page 839) was read by Dr. Arthur Hurst, who acts as chairman of the Medical Advisory Committee of the Asthma Research Council, and is in every way qualified to speak with authority. The discussion showed the very different conceptions held as to pathogenesis, and, like a collection of papers in the July number of the *Practitioner*, it lent support to the conclusion that what for convenience is called asthma is really a symptom, and that, as in the case of the epilepsies, it would perhaps be safer to speak of the asthmas. That there is no one panacea for all the forms of asthma is shown by the innumerable remedies that have been, and indeed still are, vaunted. Dr. Hurst, who in 1921 defined asthma as "a condition in which that part of the vagal nucleus which controls the motor and secretory activity of the bronchi is abnormally sensitive to chemical, reflex, and psychical stimuli," has since laid stress on the importance of a constitutional peculiarity or diathesis, without which an individual, even if hypersensitive to one or more proteins, does not suffer from asthma. The asthma diathesis, which is thus the one essential factor in the pathogenesis of the condition, is, he suggests, caused by a slight deviation from the average blood chemistry, and this is responsible for the predominance of the vagal constituent of the bronchial nervous system; further exhaustion of the adrenal glands with deficient secretion of adrenaline allows the vagal factor to get the upper hand over the sympathetic. This last hypothesis gains support from the fact that blood pressure is usually low, and from Dr. G. H. Oriel's observation that well-marked hypoglycaemia is common in asthmatics. Dr. Hurst also reiterates his opinion, formed after many trials, that skin tests are devoid of any practical value. Biochemical evidence in favour of the existence of an asthmatic diathesis is in process of being established by Dr. Oriel, who, in a preliminary communication to the July number of *Guy's Hospital Reports*, described a proteose in the urine of patients with asthma, urticaria, and some infections giving positive skin reactions.

To modify the constitutional basis for a morbid reaction is as yet a difficult problem, though Dr. Hurst considers that dietetic treatment and residence at an altitude of 4,000 feet may be effective in this direction; but he brings some destructive criticism to bear on Storm van Leeuwen's explanation that purity of the atmosphere is responsible for the beneficial influence of residence at a high altitude. In addition, attention should be directed to the avoidance of exposure to exciting factors, such as psychological and reflex stimuli, and to the elimination, as far as possible, of all septic foci. Further, emphasis was laid by the opener of the discussion on the importance of aborting an asthmatic attack at the earliest moment. With this object patients should be instructed to give themselves hypodermic injections of adrenaline solution at the first suggestion of an impending attack. Relief may thus be effected by means of a small dose, often one minim only, and this amount is not likely to cause the unpleasant symptoms that may follow the administration of the larger dose, five minims or more, which becomes necessary if the paroxysm is allowed to develop.

A "BRADSHAW" OF MODERN MEDICAL LITERATURE.

THE British Museum has been described as a storehouse of all the knowledge in the world. More accurately might it be regarded as a mausoleum wherein knowledge lies dead, to be resurrected only when, by each passage through the mind of man, it becomes infused anew with the spirit of life. To-day, more than at any period in the history of the world, it has become a matter of urgency to devise means for safeguarding knowledge against mummification in museums and libraries. In essence such mechanisms must be designed to facilitate the circulation of information, to direct facts to the minds that need them, just as the mechanisms controlling the circulation of the blood help to direct nourishment to the cells of the body.

It has been suggested that the greatest contribution the League of Nations could make to world culture would be in the creation of a central clearing-house of knowledge—an enormous organization with affiliations to every university, library, laboratory, and learned periodical in the world, in which all the facts mankind has accumulated in its exploration of the universe could be classified and indexed by staffs of highly trained workers, and diverted swiftly and easily wherever they happened to be wanted. The deliberate repetition of experiment is part of the methodology of science; the accidental reduplication of experiment, inevitable when the workers of one laboratory have no means of learning promptly what is being done in another, is a wasteful misapplication of energy. The scientific worker needs a directory whereby he could track down the scattered and newest sources of knowledge related to his own field of investigation at least as much as he does a telephone directory to his own area. Maps and gazetteers and time-tables cater for man's need of geographical orientation; there is an equally important place for charts whereby man may find his way easily through the labyrinth of knowledge. This is only to affirm that there is a sense in which, for example, a physician in London should have more ready access to, shall one say, a laboratory in Berlin, a hospital in Paris, and a library in Washington, than to his next-door neighbour. To a considerable extent his needs in this respect have been met by four admirable catalogues of medical literature: the *Index Catalogue of the Surgeon-General's Office, U.S. Army*, the *Index Medicus*, the *Quarterly Cumulative Index*, and the *Quarterly Cumulative Index Medicus*. The *Surgeon-General's Catalogue*, which has been issued regularly since 1880, and is now at letter M of its third series, includes a classification of all the medical literature, ancient and modern, to which the editors have or have had access. The *Index Medicus*, started in 1879, and the *Quarterly Cumulative Index*, started in 1916, having run concurrently during the years 1916–26, were then merged, and since 1927 the *Quarterly Cumulative Index Medicus*—the product of their union—has appeared in their place.

The fifth volume of the *Quarterly Cumulative Index Medicus* has recently been published under the auspices of the American Medical Association. It is a volume of 1,311 pages, in which lists of the books published during the period January to June, 1929, are arranged alphabetically under the authors' names and grouped according to subjects; a list is given of publishers and their addresses; and in a single index an alphabetical classification is made of all the contributors and contributions to no fewer than 1,400 of the most important medical periodicals of the world. An admirable system of cross-references and of multiple indexing protects the reader against the risk of overlooking any source of information, or failure to track down articles covering several subjects. If the work has a defect it is in the fact that the system of indexing books and periodicals separately necessitates a double search in each volume for the literature on any subject. In this respect only does it, in our view, fall short of the old *Index Medicus*, with its single subject index. It may be taken as an indication of the skill and completeness with which the editors of the *Quarterly Cumulative Index Medicus* have done their work that we have no other criticism to offer. They have given us, and we hope will continue to give us, what is in effect one of the most valuable contributions of the medical profession in America to the advancement of medical knowledge.

THE COLLECTIVE INVESTIGATION ON CANCER.

A NUMBER of reports have appeared in the lay press to the effect that "some 20,000 of the 28,000 members" have decided to participate in the British Medical Association's inquiry into the incidence of cancer and its history after treatment, of which a preliminary notice appeared in these columns on October 5th, and full details in the *Supplement* of October 26th. The latter figure much understates our membership (now 35,000), and we could wish that the former figure were not an overestimate. So far the Medical Secretary has received several hundred applications for the questionaries relating to the forms of cancer chosen for investigation, and there is reason to anticipate that even a greater number of practitioners will take part in this work than in last year's collective inquiry into the treatment of varicose ulceration. No member should withhold his co-operation simply on the ground that in the course of the year's work he sees but few cases of the conditions under investigation. It is not to be expected that a sufficient number of such cases would come within the experience of a single practitioner to enable him to draw from them any helpful conclusions about the actual evolution of cancer, its duration, and possible common factors in the medical history of cancer patients—all matters with which the present investigation is concerned. Even if he can supply details of but a single case he may make a valuable, perhaps indispensable, contribution to the investigation as a whole. There is an all too prevalent belief among general practitioners that so long as their life-work consists in the care of the sick the business of discovery must be left to others. This artificial distinction between the practitioner and the research worker reveals a failure to appreciate the true nature of scientific investigation. Science rests on a tripod of observation, hypothesis, and experiment, none of them activities circumscribed by the walls of a laboratory or limited to any subject-matter. Clinical medicine is as much a subject of scientific study as the matters dealt with in laboratories, and often it is more scientifically studied. Admittedly some of its problems come essentially within the province of the specialist; many, however, by their very nature demand solution by the general practitioner, and probably by the general practitioner only. To him belongs the comparatively little explored territory of the minor maladies, of illnesses yet at a stage when their most prominent features are disorders of function rather than gross structural change. Much has still to be learned about the origin and course of these maladies and their effect on the future health of the patient; indeed, it was for the study of these and similar questions that Mackenzie organized at St. Andrews a team of general practitioners who, by pooling their experience, might together succeed in collecting the necessary information, where each individually would be bound to fail. At the opposite extreme are the malignant diseases, and it is noteworthy that about certain aspects of these, too, the general practitioner is better qualified than anybody else to supply information that may prove to be of incalculable value. Such is the information that is being sought in the British Medical Association's collective investigation into the incidence of cancer and its history after treatment. A study of the questions makes it clear that the observations it is desired to correlate can be made far better by the general practitioner watching the whole course of an illness than by a consultant or operating surgeon under whose care a patient comes, as a rule, only for a very short time. We may once more remind readers that the Medical Secretary will be glad to answer any questions and to supply forms of instructions to members who apply to him at the Head Office of the British Medical Association, Tavistock Square, W.C.1.

TONSILLECTOMY AND RHEUMATISM.

That there are still differences of opinion about the relation between disease of the tonsils and juvenile rheumatic infection, and about the value of tonsillectomy in the prevention and treatment of this disease, is obvious from our correspondence columns. An interesting contribution to this very important subject appears in the current number of the *Archives of Disease in Childhood*, where Professor Leonard Findlay, Dr. James W. Macfarlane, and Dr. Mary M. Stevenson discuss "Tonsillectomy in the prevention and treatment of rheumatism."[1] Their material comprises 153 patients, most of whom have been under observation for five to eight years, and for the purposes of the paper it has been decided to follow the method adopted by Dr. Reginald Miller, and differentiate between patients with chorea and those with arthritis. The authors emphasize the fact that in estimating the value of tonsillectomy the exact period at which it takes place must be determined, and in this connexion they use the terms "preliminary tonsillectomy" and "intercurrent tonsillectomy," according to whether or not the operation preceded the first rheumatic manifestation; they further subdivide the second term according to the number of attacks of rheumatism which have preceded the tonsillectomy. From a first broad analysis it is deduced that though a preliminary tonsillectomy may possibly render an individual less susceptible to arthritis, the results do not lend support to the idea that an intercurrent tonsillectomy prevents recurrence of either arthritis or chorea. However serious joint affections and chorea may be in producing temporary disability in the juvenile population, they naturally are not as serious as cardiac involvement, and it becomes, therefore, of great importance to ascertain whether, even if tonsillectomy has little influence on an individual's susceptibility to arthritis and chorea, the operation in any way improves the heart's chances of escaping. In order to study this aspect of the problem Professor Findlay and his associates first attempted to ascertain the time relation of cardiac disease in reference to recurring attacks of arthritis or chorea. In the figures presented they show quite clearly that in no case in which the time of appearance of the cardiac involvement was known did this complication develop after the second attack of tonsillitis, and this was so not only in patients with chorea or arthritis alone, but also in those who suffered from both chorea and arthritis. It follows that if the benefits of tonsillectomy are to be studied in relation to heart disease of rheumatic patients, then only those cases in which a preliminary tonsillectomy or an operation before the second attack was performed can legitimately be compared with non-tonsillectomized control cases. Such a study yields contradictory results, but there does seem to be slight evidence for the view that in arthritic cases a preliminary tonsillectomy or a tonsillectomy performed early in the course of the infection may possibly render the heart less liable to attack, but not so in cases of chorea. Such a prophylactic operation must be performed before the second attack of arthritis. The matter is taken a stage further by studying the effect of tonsillectomy on the progress of cardiac conditions, and, while on the whole there is no marked evidence of the beneficial effects of tonsillectomy, the authors state that "tonsillectomy in the case of carditis following arthritis seems to have a beneficial effect on the progress of the disease, but not so in carditis following chorea." Many sweeping generalizations are being made at the present time about tonsillectomy and rheumatism, and Professor Findlay and his associates have done a valuable service in presenting such a careful analysis of this difficult problem. Their finding that patients with chorea and those with arthritis respond differently to tonsillectomy needs further investigation.

DISTRIBUTION OF RADIUM.

The Radium Commission announces that it has made considerable progress in deciding on the principles which will determine its procedure in distributing radium, and in working out the administrative machinery whereby the distribution will be effected. The radium composing the four-gram "bomb" has been received from Belgium, and this, after being measured and tested at the National Physical Laboratory, was, on November 2nd, handed over to the authorities of the Westminster Hospital. The latter, in the meanwhile, had made all arrangements for its installation and manipulation, and the treatment of patients has already begun. If at the end of the trial period of three months the National Radium Trust decides to buy the radium composing the bomb, it will be entrusted for a further period of three years (at a rental of £410 a year) to the Westminster Hospital, which will maintain with it a continuous day and night service in the pursuit of certain clinical objectives prescribed by the Commission. The Commission has decided for the present to recognize as national radium centres only such institutions as possess medical schools with complete clinical courses and facilities for instructing students and post-graduates in the principles and practice of radium therapy. The Commission holds that the need for more trained and qualified workers in the use of radium is even more urgent than the supply of radium itself. All negotiations for the constitution and equipment of national radium centres will be initiated through the medical faculties of the local universities concerned, and this procedure is now being followed. When the respective claims and requirements of the various radium centres have been considered and assessed by the Commission the allocation of national radium will be begun, and, as we announced on October 5th (p. 636), it is hoped that about three grams may be available for distribution on loan by the end of the year. The Trust has already placed orders for ten grams, exclusive of the four-gram "bomb," and the whole of this amount should be available before the autumn of 1930. The Commission estimates, however, that practically the whole of the radium which can be bought by the Trust with the funds already subscribed will be needed for the equipment of the national radium centres, and it is therefore unlikely that any of this national radium will be available for allocation to other hospitals or institutions. In accordance with the policy announced in our issue of October 19th (p. 727), it has been decided to install a radon plant at the National Physical Laboratory for the purpose of supplying, under proper safeguards and conditions, radium emanation to hospitals or other institutions which otherwise could receive no direct assistance from the Commission. Questionaries relating to this service are being framed by the Commission, and will be issued to institutions desirous of obtaining national radon and prepared to comply with the conditions laid down.

THE HISTOLOGICAL BASIS OF HEALTH.

The old Latin adage says that minute details are no concern of the law, but this, according to Professor Boeke of Utrecht, is far from being the case where the laws of health are concerned. In two Chadwick public lectures delivered last week at the House of the British Medical Association, under the chairmanship respectively of Sir William Collins and Sir James Crichton-Browne, Professor Boeke gave an illuminating exposition of the histological basis of health, dealing in his first lecture with the tissues in youth and age, and in his second with the nervous system in relation to health. He argued that, since the normal functioning of different parts of the body depends on the structure of the tissues and their component elements, the problem of health ought to be approached from a histological standpoint, each organism being an entity in itself. Analysis

was not the last word in science; the final step was a synthesis of scientific conceptions and deductions. One of the most interesting phenomena in human physiology, he remarked, was the formation of the different hormones which circulated in the blood and influenced the action and growth of cells; differentiation in a given direction could, indeed, be induced in certain tissues and cells by the injection of hormonic substances. The vital actions of the cells depended largely on the chemical processes going on in the living protoplasm, and the cellular units of the reticulo-endothelial system had peculiar chemical properties by which they could influence other cells. It followed that old age was an aspect of development; a general change of all the tissues in the direction of atrophy, with disappearance of the ability to repair what was lost. Growth and senescence could be formulated as a series of chemical processes which might be expressed by mathematical formulae. When, however, the factor of tissue differentiation was taken into account, growth began to lose its mathematical formulation and its identification as a chemical process; death was the result of differentiation, and the non-differentiating tissue culture might be practically immortal. Development was nothing but differentiation, and the hormones played a most important part in health, in tumour growth (the "auxetics" of Ross), and in other pathological changes. In his second lecture Professor Bocke illustrated these characteristics of growth and differentiation by reference to the central nervous system—the most highly differentiated tissue of the human and animal body, and exhibiting most clearly the chief factors in growth and development. Two kinds of cellular elements existed in the nervous system—the nerve cells, and the neuroglia or connective tissue elements. In old age a contest between these two seemed to develop, culminating in the curious phenomena of "neuronophagy," the eating up of the ganglion cells. Studied closely, this process was seen to be an effort to re-establish the harmony destroyed by the now lessening activity of the senescent nerve cells. This harmony between form and function of the nervous system was most plainly shown by the rapid development of the functional structure of the cerebellum in birds; the structure needed to enable the newly hatched chicken to act as an independent individual was developed within twenty-four hours. During the life of the organism the nerve cells remained unchanged, the only changeable elements being apparently their synapses, which could alter the paths of the stimuli and the rapidity and strength with which these were conducted from one element to another. So, Professor Bocke concluded, study of these details compels the assumption of a perfect continuity of all the elements of the nervous system, of a perfect harmony, a perfect equilibrium of the component parts, of the "interpenetration of all by all," as being the primary factor in healthy normal life.

VETERINARY EDUCATION.

Some months ago there was issued the report of a Colonial Office committee on veterinary education in connexion with the development of the non-self-governing possessions, and a few days ago the report of another committee on veterinary matters was published. The latter dealt with the condition of the Royal Veterinary College in London, and with undergraduate rather than post-graduate education. Both reports have one feature in common—a sweeping condemnation of the state of the buildings in Camden Town. The latest report, in fact, goes so far as to state that "the condition of the Royal Veterinary College is a national disgrace. The building is for the most part in a state of dilapidation, and much of it has been condemned by the local authority as a dangerous structure." Britain in matters veterinary is in a peculiar position. It is the most important stock-breeding country in the world—especially bloodstock—and the Briton has a higher ethical conception of animal life than any other race. Yet, so far as public support and financial encouragement are concerned, veterinary education and research is more neglected here than in practically any other important land, and it is only because of the altruistic enthusiasm of a few that the British veterinary diploma is still regarded as one of the foremost in the world. There are, however, signs that a new interest is being taken in the subject. The Royal College of Veterinary Surgeons a few years ago raised the entrance requirements for the study for its diploma to the Arts standard; more recently it has agreed to extend the period of professional education to five years. The Colonial Office report proposed a comprehensive scheme of post-graduate education and research, and made recommendations as to pay and status which would encourage the best type of men to enter the colonial veterinary services. In the near future, therefore, there should be an increasing demand for adequate undergraduate training facilities. The present report makes many concrete proposals towards providing these, and placing the London college on at least as good a footing as, say, the Edinburgh college (although even there extensions are urgently required to meet the growing demand for veterinary education). It is proposed that the present buildings in Camden Town should be razed to the ground, and that entirely new buildings, costing about £300,000, should be erected in their place. The annual maintenance charge for these new buildings would be in the neighbourhood of £30,000. In addition, the Institute of Animal Pathology, which is housed in a new building (which it is not proposed to touch), and receives an annual grant of £5,000 from the Ministry of Agriculture, should be provided with facilities for conducting work in the field; a sum of £25,000 is necessary for this purpose, together, of course, with an increased annual maintenance grant. The reconstituted college should form a school of London University, a course which would not only enhance the status of the college, but would bring its students into much more intimate contact with those in other branches of learning. The medical profession in Britain in recent years has found that much good can come from a closer co-operation between the two branches of the greater medicine, and study of comparative medicine has proceeded faster and in a more satisfactory manner in this country than elsewhere. An adequately equipped veterinary school in the University of London would do much to foster that growing co-operation, and make the results more valuable to both professions.

FOOD ADULTERATION.

Public health legislation during the last half-century has done much to ensure that foodstuffs are fairly pure. In particular it has practically abolished dangerous adulterations and also the cruder forms of adulteration. The fact that gross frauds have little chance of escaping detection does not mean, however, that food adulteration is a danger of the past. Dr. Ainsworth Mitchell, the editor of the *Analyst*, in a recent article[1] gives an interesting account of some of the up-to-date methods of the food adulterator. He points out that "each fresh advance in analytical methods has been countered by corresponding applications of scientific knowledge on the part of the adulterator. His aim has been to make a product which shall be on the borderline between a genuine article of poor quality and an adulterated article which might often conceivably be genuine." The great difficulty in stopping this type of fraud is that pure natural products are subject to wide variations. This is especially important in the case of milk. The institution of a statutory standard for milk has

[1] C. Ainsworth Mitchell: *Police Journal*, vol. II, No. 8, p. 546.

been followed by an increased frequency of milks just within the statutory limits. Moreover, when the milk is on the wrong side of the line the vendor has a second line of defence, the "appeal to the cow," for, according to Dr. Mitchell, "since the case of Hunt v. Richardson, which was decided in the High Court in 1916, a vendor may sell as milk any milky fluid which he can induce his cow to produce." This makes it safe to feed the cow so as to produce the largest volume of milk, irrespective of quality; and the chief change from former practices is that the milk is diluted "at the other end of the cow." Many of the modern changes under the Food and Drugs Act involve questions of correctness of description rather than that of simple adulteration. The following are examples of the problems raised. Does "raspberry jam, improved by the addition of a little fruit juice," correctly describe apple jelly with a few raspberries added to it? Is a mixture of citric acid, glucose, syrup, margarine, lemon flavouring, and artificial colour properly described as "lemon cheese," or maize starch, coloured with a dye and with the addition of a small amount of dried egg, as an "egg powder"? These examples indicate the manner in which modern commercial enterprise tries to keep within the limits of the law, but at the same time to make a profit by selling to the poorer sections of the community inferior food substitutes. The only defence of the community is a vigorous administration of the Food and Drugs Act, and this depends on the local authorities. The variations quoted by Dr. Mitchell in the administration of these Acts are very remarkable. In one county in 1927 only seven official samples of foodstuffs were taken, and of these three were found to be adulterated. In two populations of an equal size, one, a county, took forty official samples, whereas the other, a borough, took 725 samples. These figures certainly suggest that if the populations of many areas get unadulterated food they have to thank luck rather than the local authorities.

INDUSTRIALISM v. RURAL BEAUTY.

There is much that is attractive to the cynical mind in the contest which is arising between industrialism and rural beauty. After the war the first instinct of the politician was to make this country a fit home for heroes to live in. For this purpose it was necessary to build innumerable houses; but no one troubled his head with the question where these houses were to be placed. At the same time the development of motor traffic necessitated the provision of wider and better roads; and another batch of our rulers concentrated their attention on cutting by-passes and arterial thoroughfares through the peaceful countryside. Then there arose a demand for cheap power to enable trade to flourish, and to provide the wherewithal for the workers to pay some portion of the rent of the houses they lived in. Suddenly it was discovered that this mighty pageant of "progress" was leading to the destruction of much of the beauty of the country. Consequently we now find eminent statesmen advocating in their speeches the decoration of rural districts with vast armies of pylons, while they write to the newspapers imploring landowners and builders not to deface the scenery. In this curious situation it is left to voluntary private bodies to endeavour to collect sufficient funds to preserve some remnant of beauty for the pleasure of posterity. For this purpose Cambridge has followed the example set by Oxford, and has formed the Cambridge Preservation Society on the lines, and with the help, of the Oxford Preservation Trust, to whose second report we called attention on February 23rd last (p. 363). Those who in these days approach Cambridge from the south cannot have failed to be shocked by the horrible row of "ribbon development" tenements which have sprung up between Shelford and Trumpington. In the pamphlet issued by the Preservation Society when appealing for funds a photograph of a portion of this nightmare is reproduced; and, although the beauties of this stretch of road cannot be said ever to have been transcendent, its present condition is ample cause for the formation of the society in March, 1928. The efforts of the founders turned first in the direction of Madingley, from whose hill the view of Cambridge is certainly the most beautiful. A few years ago a row of chicken huts arose to break the skyline, and more recently boards announcing building sites began to be replaced by the inevitable bungalow. With the help of Colonel Ffenell, of Wytham Park, near Oxford, and of Professor Trevelyan, the society has now stepped in, and has bought 380 acres of land, including the south side of Madingley Hill. Moreover, it has obtained the sympathy of Mr. Harding, who owns the north-eastern slope of the hill, so that the preservation of Madingley from the fate of the Shelford road is practically assured. It is hoped that the society will be able to preserve existing footpaths in the neighbourhood of Coton, and to form others where its control of land makes such action possible. In the meantime, an attempt is being made to induce the county council to help in covering up the Shelford road "development" with a mask of trees; a group of picturesque houses at the corner of Northampton Street and Magdalene Street has been bought by a generous member of the society; and the importance of fine design in their new dwellings has been urged upon owners of property in the town itself. In the future it is hoped to do something to preserve the charm of many of the villages which lie round Cambridge. It is pleasing to learn that the society maintains cordial relations with the local authorities, and with such bodies as the Cambridge Antiquarian Society, the Rural Community Council, and the Council for the Preservation of Rural England. It is curious to reflect how much destruction of the beautiful is involved in the "progress" of civilization. To many it must often seem that the choice of sites for industrial development is, to say the least, indiscreet. How otherwise are we to account for the founding of factories in University towns? But progress means money, and it is not to be expected that the landowner will readily refuse tempting offers for the purchase of sites for factories, pylons, or bungalows. It is well, therefore, that private bodies should do what they can to preserve some balance between the material and the spiritual needs of man. The Cambridge Preservation Society, like the Oxford Preservation Trust, is worthy of support and sympathy, and not least from its medical graduates.

DENTISTRY AT THE MAYO CLINIC.

Dr. Boyd S. Gardner, head of the dental section of the Mayo Clinic, lectured to a crowded theatre at the Royal Dental Hospital, London, on November 4th, chiefly on the organization of the section, which he formed eleven years ago at the request of the brothers Mayo. He began with a tribute to the excellence of the dental technique which he had seen on this side of the Atlantic. He said that he had just completed a visit to several countries of Europe, and was taking back with him many new ideas. In Scandinavia (where 40 per cent. of the dentists were women) he had been astonished to find what a high level preventive dentistry had reached; it was better than the average in America. He had been equally impressed by the progress in Southern Europe. In Spain, which had been thought of as a backward country from the dental point of view, there was about to be built the world's largest dental college; and in Rome, thanks to Signor Mussolini's insistence on dental hygiene and Mr. Eastman's benefactions, he had felt as nowhere else the driving force of high ideals in dentistry. Coming to his own work at Rochester, Minnesota, Dr. Gardner likened the organization of the Mayo Clinic to the spokes of a wheel, all radiating from the hub. The closest co-operation was maintained

between the dental section and the other sections dealing with general medicine and surgery, and consultations constantly took place over referred patients, in which sometimes as many as eight representatives of different departments would assist. No replacement, filling, or bridgework was done at the clinic, the work was limited to diagnosis and surgery. In America the surgery of the mouth had been belittled for generations, and four-fifths of the income of dentists was derived from replacements. The Mayo Clinic was trying to place dentistry on the same plane as surgery. The dental student was instructed, when he looked into a patient's mouth, not to think first of all what could be done in the way of a bridge or a filling, but to have regard to the cause of the condition. The different departments joined forces to discover and eliminate focal infection. Dr. Gardner gave several instances of the way in which dental infection had been found to play the controlling part in disease elsewhere in the body. Records had been kept of a hundred cases of ulcerative colitis treated at the clinic from the standpoint of eliminating some distant foci of infection, principally in the teeth, though often also in the tonsils; cures were effected in fifty of the cases and improvement in thirty others, although many of them were of long standing. Retinitis and many other conditions, as well as certain types of arthritis, had been found to clear up after the focal infection in the teeth had been removed. By means of lantern slides Dr. Gardner described the working of the clinic. He spoke of the dental chair as an antiquated relic. It had been difficult to get the American dentist to give up this piece of furniture, but in the Mayo Clinic for any serious work on the mouth the recumbent position on the couch was obtained. X-ray examination was insisted on as a routine procedure, both before and after any operative measure. Exposures were standardized, so that the work in the dark room could proceed with almost mechanical regularity. He also showed specimens of the elaborate charts used for reporting on the patients, and added that the clinic worked in close association with the local dentists.

THE Nobel Prize for medicine for 1929 has been divided between Sir Frederick Gowland Hopkins, M.B., F.R.S., professor of biochemistry in the University of Cambridge, and Professor C. Eijkman, M.D., of Utrecht, Holland, for discoveries in connexion with vitamins.

THE next session of the General Medical Council will commence at 2 p.m. on Tuesday, November 26th, when the President, Sir Donald MacAlister, Bt., K.C.B., M.D., will take the chair and give an address. The Council will continue to sit from day to day until the termination of its business.

THE Semon Lecture, entitled "The lower end of the oesophagus at birth and in the adult," will be delivered in the Barnes Hall of the Royal Society of Medicine, 1, Wimpole Street, W., by Dr. Harris P. Mosher, professor of laryngology in Harvard University, on Thursday, December 5th, at 5 p.m.

FOR some time past the X-Ray and Radium Protection Committee, with Sir Humphry Rolleston as chairman, has had under consideration methods whereby hospitals may be protected from fire caused by the combustion of x-ray films. The committee made preliminary suggestions to this end in a letter published in our columns on June 8th (p. 1057), and it has now issued some detailed recommendations on the handling and storage of celluloid x-ray films. We hope to find space for these recommendations in an early issue.

INTERNATIONAL SOCIETY OF MEDICAL HYDROLOGY.

Annual Meeting in Hungary.

THE annual congress of members of the International Society of Medical Hydrology was held this year in Budapest, from October 13th to 18th, by invitation of the Hungarian Government and of the University of Budapest. The International League for Combating Rheumatism, an offshoot of the society, also held its annual meeting in conjunction with them. In all, twenty-four nations were represented, official delegates being nominated by most Governments. This would seem to be an indication of the awakening interest which is being taken in the subject of rheumatism and arthritis throughout Europe, due, presumably, to the realization of the part it plays as a disease of great industrial importance.

The fifteen English representatives were joined in Brussels by the representatives of Holland, France, and Belgium. In spite of the early hour of their arrival at Budapest (6.15 a.m.) they were met at the station by a deputation headed by Professor Vamossy, and conducted to their hotels. The council was later invited to lunch by Dr. von Dalmady, professor of balneology in the University. The same evening the Hungarian Balneological Society, under the presidency of Dr. von Vamossy (professor of therapeutics), entertained the congress in lavish style at the Ritz Hotel.

On Monday, October 14th, the congress was formally inaugurated in the Great Hall of the Hungarian Academy of Sciences. The opening address was delivered by the chairman of the International Society, Dr. R. Fortescue Fox, who introduced the president for the coming year—Baron A. de Korányi, professor of medicine in the University of Budapest, and senior physician to the University hospital. Speeches of welcome were then made by the Minister of Social Welfare on behalf of the Government, the Lord Mayor of the city, and the Dean of the Faculty of Medicine. A letter was also read from Lord Dawson of Penn, the retiring president, regretting his absence.

Action of Hypertonic Waters.

The first medical discussion, on the action of hypertonic waters, was then introduced by Professor Dalmady, who stated that, given a sufficient concentration, the effect of all hypertonic waters was similar, since the chemical factor could be discounted, and only the osmotic factor counted. In naturally occurring hypertonic waters, however, this concentration was never reached, and the chemical composition of the waters must therefore be taken into account when considering the indications for each type of water, owing to the absorption of the various chemical ions. This had the effect of extending their therapeutic uses to such conditions as arthritis, which have long been known to benefit by their use.

Professor Pinilla (Madrid) read a paper on recent research he had conducted on the effect of hypertonic waters on an isolated loop of intestine. He was of the opinion that their action was not purely osmotic, but that the integrity of the local nervous system was essential. He mentioned the view of Sanarelli that the purgative action of salines was due to the stimulation of the nervous network by the dissociated ions in the body fluids. This view was further emphasized by Dr. Harpuder (Germany), who stated that the saline ions appeared to be reabsorbed in the intestine to an extent determined by their diffusibility. He found also that although reabsorption did not take place from the stomach, yet the gastric juices were largely stimulated by solutions of moderate concentration. Dr. Fortescue Fox (London) referred briefly to the effect of these waters on the "congestive disorders of middle life." This paper was discussed briskly by representatives of most spas which have experience with this type of case, with the notable exception of Harrogate, which was unrepresented at the congress.

The members were then taken to see many of the chief sights of the old town; after lunch they inspected the well-known "Hunyadi János" springs, and were shown a cinema film representing Hungarian life and customs. They were entertained to dinner in the evening by the Royal Hungarian Government, when speeches were delivered by the Minister of Social Welfare and Labour, Professor Dietrich (Berlin), Dr. Fortescue Fox (England), Dr. Ferryrolles (France), and Senator Professor Gabbi (Italy).

Hydrotherapy in Cardio-vascular Disease.

On the next day the subject for discussion was the use of waters and baths on cardio-vascular disease; it was introduced by Dr. Schmidt (Hungary), and continued by Dr. Mougeot (France), who spoke as one who had had twenty-five years' experience of this type of treatment. He believed that the cardiac patient benefited considerably from carbon dioxide bath treatment, but not in most cases from the ingestion of waters. During the discussion the general opinion appeared to be that this type of treatment was very useful in all forms of heart disease which were not attributable to any curable cause—for example, digestive arrhythmia—and in which the compensation was not good. Arterial hypertension, with or without cardiac involvement, was also considered to be an indication, unless the pressure was extremely high. Sir Thomas Lewis's work on the capillaries was discussed.

An excellent demonstration of cases of arthritis, illustrating his classification, was given by Dr. L. von Papp, who later showed the congress his methods of treatment by mud and physiotherapy at the St. Luke's bath, where there is a natural hot-mud lake of 500 metres square; round it there is built one of the many palatial hydrotherapeutic establishments of Buda. Later in the afternoon tea was taken at Dr. Jakabo's magnificent sanatorium in the mountains which surround the city. In the evening a gala performance of Poldini's *Carnival Wedding* was given at the Opera.

Research in Rheumatism.

On October 16th the International League for Combating Rheumatism arranged discussions on the relation between acute and chronic rheumatism in the various countries, and on the haematology and serology of rheumatism. In the second discussion Mr. Joseph Race (Buxton) read an excellent and interesting paper embodying his researches at the Devonshire Hospital. He considered that but little information could be obtained by means of the blood count, but that the suspension stability curve was of the utmost importance in every case of arthritis, both prognostically and as an aid to correct diagnosis. Dr. Zimmer (Berlin) read a valuable record of research on the endocrine aspects of arthritis, and emphasized his belief in the importance of the Arneth count. Dr. Van Breeman (Amsterdam), honorary secretary, produced a large number of records of blood counts made during the last ten years on rheumatic patients, for comparison with others; he appealed for an international uniformity of nomenclature in these matters, as did also Dr. Kahlmeter (Sweden).

At midday the congress went up to the Royal Palace, where they were received by His Highness Admiral Horthy, Regent of Hungary, who expressed his pleasure at the society's choice of a meeting-place this year. In the evening, at the invitation of the Government, the magnificent Agricultural Museum was visited for the purpose of sampling the various Hungarian wines; this proved an extremely popular fixture.

On October 17th a general meeting of the society was held at the St. Géllert Hotel. It was decided that the annual congress next year should be held in Lisbon, by invitation of the Government. Lunch was then taken, by invitation of H.R.H. the Archduke Francis Joseph, the chief speeches being those of the Archduke, Professor Korányi (president of the International Society), Dr. J. Burt (England), and Professor Taipale (Finland). Later, members of the congress were taken up the Danube by boat, returning in time for the farewell banquet given by the Lord Mayor of the city, which was followed by a dance.

The official congress being over, many members availed themselves of the invitation of Professors Stresser and Freund to spend two days in Vienna to study the treatment of the rheumatic diseases in a city which had not the advantage of being provided with natural waters of curative value. The members were received at the Wenckebach clinic; a number of cases of arthritis were demonstrated by the representatives of four countries, and notes were compared. Later the party was welcomed in the Rathaus by the Burgomeister, who was gracefully thanked by Dr. C. W. Buckley (England). After lunch the sights of the city were visited, including several establishments for the treatment of arthritic patients insured by the friendly societies of the various trade unions. These establishments are of the type of the "centre" now being built for this purpose in London by the British Red Cross Society; moreover, research work is largely subsidized.

Australia.

A Study of Mental Deficiency in Victoria.

During the last few years the anatomy department of the Melbourne University has received from the Edward Wilson Trust financial grants in aid of scientific and clinical studies into the subject of mental deficiency. These grants come to an end this year, and an extremely interesting report of what has been done has just been furnished by Professor R. J. A. Berry.[1] Earlier work had been done jointly by Professor Berry and Mr. S. D. Porteus, who, with Miss Temple, was seconded to the University department from the Education Department of the State of Victoria, for the years 1917 and 1918. Their researches were directed mainly towards the ascertainment of the normal rate of brain growth in the normal boy and girl, and of any association of deficiency of mental development with physical growth. Mr. Porteus is now professor of psychology in the University of Hawaii, and his development of these earlier researches whilst research director at Vineland, New Jersey, is well known. Professor Berry has continued the work in Melbourne, and his methods and conclusions are of the highest importance. Reference may be made to his article on "Brain and mind" in the *Journal* of April 19th, 1924 (p. 707), and to his book with the same title published by the Macmillan Company last year. In those publications are explained the procedure and clinical methods which Professor Berry has adopted, and which he has followed in the 1,541 cases dealt with in this report to the Edward Wilson Trustees. These cases were mainly children and adolescents, but included some adults. They were gathered from various hospitals, institutions, or welfare departments. Both sexes were represented, but the males were nearly twice as many as the females. In each case the usual medical history—personal, family, and ancestral—was obtained. The scholastic or educational work of each was investigated. The social and environmental conditions were very fully gone into and taken into account. Then the various tests, physical and mental, on which Professor Berry relies were applied. They are: cubic capacity of brain, standing stature, sitting stature, weight, right grip, left grip, vital capacity, Binet tests, Porteus tests. Professor Berry admits that the methods which he and others have adopted for "cubing the living human head" are imperfect, even "somewhat crude," and he emphasizes that such tests should "never replace the most attentive study of the individual." But he is convinced "first, that special clinical methods are essential in the diagnosis of the amentias; second, that these methods should not replace ordinary medical methods of examining the nervous system, but should be an addition to the same; and third, that the diagnosis should be solely in the hands of the medical profession." This third point is of considerable importance just now, when it is sometimes claimed that the teacher alone can make a correct diagnosis. It is true that many of the lower grades—the idiots and imbeciles—can be recognized with ease even by the untrained, and that in all aments the taking into account of any educational experience is of the greatest importance; but many of the higher-grade aments, the much more socially dangerous feeble-minded, pass unnoticed even by the medical profession. Professor Berry claims that his experience and the statistics detailed in this report have shown that it is precisely in these cases that the tests and measurements mentioned have proved their value. As regards head size, he says, "it appears to be definitely established that at least two-thirds of mental defectives are, or tend to be, distinctly microcephalic"; and "the mentally abnormal are much more irregular in their brain growth than the normal, have a pronounced resting phase in this growth about the

[1] 1929. Melbourne: *Argus* Office, Melbourne, Victoria.

age of puberty, and never catch up to the normal." The value of the other tests combined is assessed, and they are credited with a high degree of usefulness. No reference is made in the report to Dr. Lewis's investigations for the Departmental Committee (possibly the report was written before the results of these investigations could be read in Australia), but Professor Berry agrees that "it is certain that the incidence" of mental deficiency "is much wider spread than previous statistics would lead us to believe." His report should reinforce the urgent demand for further inquiry and action on this matter, and must surely spur the State of Victoria at once to supply its woeful legislative and practical needs in this connexion.

New Home for the N.S.W. Branch.

On September 7th the foundation stone of the new building to house the offices of the New South Wales Branch of the British Medical Association was formally laid by Sir Ewen Maclean, Past-President of the British Medical Association. Advantage was taken of Sir Ewen Maclean's presence in Sydney, while attending the Australasian Medical Congress, held there during the week, to ask him to perform this ceremony. The New South Wales Branch of the Association up till recently occupied its own premises in Elizabeth Street, Sydney. These being resumed by the city council, the Branch has, for the time being, been located in offices in the Government Savings Bank in Castlereagh Street. The site of the new building is in Macquarie Street, Sydney. It is to be a building of twelve stories, housing the offices and library of the Branch, and it will, in addition, have offices for some hundred tenants. The building will probably be finished by the middle of 1930. Dr. F. Brown Craig, president of the New South Wales Branch, presided over the ceremony, and gave a brief address outlining the history of the movement to provide this new permanent home for the offices of the Branch. After declaring the foundation stone well and truly laid, Sir Ewen Maclean gave a short address, felicitating the members at the New South Wales Branch on the site that they had chosen, and wishing them every success in their new premises. Dr. W. A. Crago, honorary treasurer of the New South Wales Branch, and Dr. R. H. Todd, honorary secretary, proposed a vote of thanks to Sir Ewen Maclean, and expressed their pleasure in the association of the parent body with the New South Wales Branch by the kindly consent of the immediate Past-President of the British Medical Association to perform the ceremony.

The Hospital Act.

The new Hospital Act for New South Wales has been assented to and is now in operation. The main features of this Act are, the appointment of a Hospital Commission, with a full-time officer as chairman, to correlate the working of all hospitals, to decide the types of hospitals to be established, and to allocate any Government fund according to subsidies. The system of voluntary contribution is to be maintained. The hospitals are to have the right to charge the patients according to their means and the services rendered, and also to have the power to sue for such failure to pay. The commission may, at the request of any hospital, hold an inquiry as to whether it is desirable that any portion of the hospital should be set apart for the admission and treatment or persons able to pay for, and who may contract with the hospital to provide for, intermediate accommodation, and, after inquiry, authorize the setting apart of any such portion. The regulations may provide for the establishment, by agreement between employers and employees, of industrial contribution schemes. It is hoped that this will be a great advance on the previous legislation, in that, while continuing the principle of voluntary contribution, that side of the work which is performed as a charity will be maintained. It will enable the hospital to charge and obtain payment from those people who are able to afford to pay something, and so will prevent the abuse of charity. It will also enable a scientific scheme of hospitals to be established according to the needs of any district, and, further, will facilitate the establishment of the community hospital, where patients graded in accordance with their incomes can be treated under the best hospital conditions.

England and Wales.

Lord Moynihan's Address at Burnley.

At the opening of the new radium clinic at the Victoria Hospital, Burnley, on October 28th, Lord Moynihan delivered an address on the cancer campaign in this country. To a medical man, he said, Burnley was sacred ground, for in that town lived Sir James Mackenzie, one of the greatest physicians of all time. It was a simple fact, he continued, that surgery in its attack upon cancer had reached its limit, and as one in seven over 30 years of age died of cancer it became imperative that something more should be done. While the general mortality rate had been lowered 32 per cent. in the last twenty years, the death rate from cancer was increasing, and during this century alone no fewer than twelve million people in the civilized world had lost their lives from this disease. In two ways could the attack on cancer be made more effective —by education and research. He had occasionally been told by colleagues that it was not wise to talk of cancer to the public, because it would excite fear in the hearts of those who listened. He himself feared nothing in the world that he understood; fear was a quality of ignorance, and if the public could be enlightened about the bitter but not wholly unfavourable truth, much would be done to help them. It had been suggested that by his statements he had frightened the public to death, but he recalled the fact that following an address he had given some time ago to a lay audience a number of persons had consulted doctors and been relieved of cancer by an operation at an exceptionally early stage. Instead of frightening people to death, said Lord Moynihan, he had been frightening them to life, which was a much better thing. On the subject of education he said that people had such erroneous ideas about cancer that no sooner had the medical profession started its cancer campaign than the quack was able to start his; when he read the quack advertisements it made him almost wish to be suffering from the disease in order that he might undergo the swift magical cure the quack had to offer. The incredulity of people had also to be dealt with. Cancer was being cured every day by surgical methods, yet many persons thought that if a growth was operated on it would inevitably recur. Yet research into treatment for cancer of the breast had shown that where the tumour was limited to the organ involved 60 per cent. of patients were alive and well ten years after the operation, without a sign of cancer. Emphasizing the need for research work, he said that many cases of cancer of various organs were now being treated by radium in expert hands with a success which sometimes equalled, and sometimes surpassed, the best the surgeon could do. Radium, however, was a dangerous remedy, and he was delighted, therefore, that in Burnley they were putting their clinic into the hands of experts, who could control such factors as the amount to be administered, the frequency of administration, and the length of exposure. In this way they could carry out valuable research work side by side with the treatment. To the individual suffering from cancer it was all the world to him that he should be cured, but behind the individual was the mass of people, and in the treatment of every individual case it was essential that such research work should be carried out as would increase knowledge and strengthen the doctors and physicists in their attack upon future cases.

Health in Industry.

The Industrial Health Education Society was founded in 1925 for the purpose of teaching the workpeople of this country how to prevent or at least mitigate sickness and disability arising in the course of their employment. Its honorary president is Sir Humphry Rolleston, and the president of the London area Sir Thomas Horder; the offices are at the B.M.A. House, Tavistock Square. One of the main activities of the society is the provision of health talks by arrangement with the workers' organizations of various industries. Since 1925 more than a thousand of these informal addresses on occupational diseases, accident prevention, and personal hygiene have

been given on behalf of the society by members of the medical profession. The society's work is, however, hampered by lack of funds, and in order to stimulate interest and support a luncheon was given at the Carlton Hotel, London, on October 31st, by Lord Melchett. The company included prominent industrialists and trade union leaders, and among the medical guests were Lord Dawson, Sir Humphry Rolleston, Sir George Newman, Sir John Rose Bradford, Dr. H. B. Brackenbury, Dr. Robert Hutchison, Dr. Charles Porter, Dr. James Fenton, and Dr. G. Clark Trotter. In proposing the toast of the society Lord Melchett declared his belief in the importance of the work it was doing. As one with great experience among industrial workers he was convinced that lectures on health matters were invaluable, and the doctors who gave their services in this way deserved the gratitude of all. He hoped that the society was exercising an educative influence upon the employers too, for they were quite as much in need of guidance. The average citizen's knowledge of health matters was still in an extraordinarily primitive state, and it was disappointing to find how few workpeople in this country took advantage of the facilities which enlightened employers provided for them. In reply to the toast Sir William Milligan, chairman-elect of the society, gave an account of the work accomplished during the past four years among workers in varied occupations. He explained that the health talks were not formal lectures, but rather an exchange of opinion and thought between medical men with intimate knowledge of the subject and men and women engaged in particular occupations. In order to continue and extend this work the society needed a larger measure of sympathy and help from the employers of labour. In proposing the health of Lord Melchett, Mr. Ben Tillett, M.P., remarked that the last thing the average employer thought about was the sanitary convenience and the needs of his workpeople, and that the last thing the workers themselves thought about was the same question. He looked forward to the day when both worker and employer would acquire a real sense of the value of human health.

Freedom of Kingston-on-Thames Conferred upon Dr. R. N. Goodman.

The freedom of Kingston-on-Thames was presented, on October 16th, to Dr. R. N. Goodman, in view of the very distinguished services he has rendered to the Royal borough. In making the presentation the mayor stated that Dr. Goodman had been one of the original members of the education committee, which was appointed in 1903, but before that he had served on the board of governors of the local endowed schools, and so far back as 1893 was on the committee of the old public schools dealing with elementary schools; to this committee he was secretary in 1895. Although Dr. Goodman had been primarily interested in technical education it was probably to the secondary schools that his services had been rendered more fully. Thus in 1904 he took an active part in raising money to preserve Kingston Grammar School and to place it on a sound financial basis. The school was largely indebted to him for its spacious playing fields and the preservation of its chapel. Tiffin School also owed much to Dr. Goodman, who had been energetic in promoting the erection of a new school, which would soon be opened. He had represented the borough on the Surrey County Council, and had been active in supporting the work of the Victoria Hospital and the Kingston Nursing Association. His generosity had been largely responsible for the purchase of the Kingstonian Football Club ground, which would be a great asset to the borough. Dr. Goodman, replying, referred to incidents connected with the progress of educational facilities in Kingston-on-Thames, and commented on the excellent assistance to the borough that had been rendered by various other members of the local medical profession. At the subsequent mayoral dinner a warm tribute was paid by Sir George Penny to Dr. Goodman for his magnificent work on behalf of education, which had well entitled him to the honour of being one of the seven freemen of the borough. Dr. Goodman, in returning thanks, mentioned that the only living freeman of the borough beside himself was Lord Baden-Powell, and he commented on the fact that in both cases the distinction might be said to have been conferred by reason of special interest taken in education. In an editorial article in the *Surrey Comet* for October 19th, the conferment is described as "a definite and spontaneous expression of civic appreciation of real worth, richly deserved by one who has not sought it in anything he has ever done for the town of his adoption."

Blood Transfusion Service in Oxfordshire.

As the result of a public meeting held at the Radcliffe Infirmary in June last, a branch of the Blood Transfusion Service of the British Red Cross Society has been established in Oxford. The meeting was convened by the county director (Dr. F. G. Gardner) following a request by the infirmary authorities to the Red Cross for help. The mayor presided, and Mr. Oliver, the honorary secretary of the parent organization, who has done so much to help the cause of blood transfusion, gave a lucid and interesting address. Members of the honorary staff explained the technical and scientific aspects of the subject, and as they will administer the service, nothing will be lacking in the way of care and skill. A number of volunteers have offered themselves, and have been "grouped" and registered, and it is hoped that an adequate service is now definitely formed for the district. The rover scouts, as in so many other places, have been most helpful, and many of them have been placed on the register. It is unnecessary to-day to refer to the importance of blood transfusion as a life-saving measure. Under the auspices of the British Red Cross Society branches of this service are coming into being all over the country and they help to carry on one of the many, and by no means the least important, of the society's activities. The increasing usefulness of the service is illustrated by the growth of the London branch; this was formed in 1921, in which year it served only one case. In 1922 the figure had risen to thirteen, and the following figures represent the cases served in the years from 1923 to August, 1928, inclusive: 12, 62, 428, 727, 1,293, and—for eight months of 1928—840.

King Edward's Hospital Fund for London.

Evidence that the voluntary hospitals are still strengthening their hold upon the confidence of the general public will be found in the statistical review of the work and finance of the London hospitals for 1928, which has been issued by the King Edward's Hospital Fund for London. In place of its familiar reports in previous years, the Fund has now decided to record this information in two publications, one being a statistical summary of the income, expenditure, work, and costs of these hospitals, and the other a statistical review of the work and finance of the London hospitals. Each of these can be obtained from the offices of the Fund, 7, Walbrook, E.C.4, the price being 1s. net. The review for 1928 opens with a table showing the expansion of hospital work during the last five years. The average number of beds occupied has increased from 11,350 in 1924 to 12,980 last year; there have been similar increases in the numbers of new in-patients, new out-patients, and the total out-patient attendances. The bed complement was increased by 600 during 1928, and represents an advance of 1,600 since 1924; the average period of residence of each patient in hospital has fallen steadily. The total income of 136 London hospitals amounted to £3,424,000 in 1928, which compares with £3,267,000 in the previous year. The principal increases were: £143,000 in donations and £68,000 in receipts from patients, but the legacies decreased by £80,000, the lowest total received from this source in the last five years. Details of the sources of income are depicted clearly by coloured graphs, and a new feature in this year's review is a diagram of a medicine bottle indicating the total general expenditure of the 136 hospitals, and the proportions of this which are provided by income from investment, receipts for services rendered, and the voluntary gifts required to meet the resulting deficiency. It is interesting to note that, though both the income from investments and the receipts for services have been steadily increasing, these sources provide each year approximately the same

proportion of the expenditure which has correspondingly risen. In 1928 the daily expenditure of the hospitals was over £9,000, and to meet this an increment of more than £4,500 was required from voluntary gifts. In short, the financial difficulties of the hospitals in recent years are shown to have been due, not to diminishing income, but to steadily increasing expenditure consequent on the expansion in the volume and changes in the character of hospital work. Thus, the expenditure for 1928 increased by 6.6 per cent. over the previous year, and by about 18.4 per cent. over that in 1924; the beds occupied increased by 4.4 per cent. over 1927, and 14.4 per cent. over 1924; while out-patient attendances rose by 5 per cent. as compared with 1924. The increase in the volume of work done was accompanied by a relatively as well as actually higher expenditure; this is referable to the additional benefits given by the hospitals as a result of the advances made in medical and surgical practice. The total general fund income has exceeded expenditure in each of the five years, but the balance is steadily diminishing each year, and was considerably smaller in 1928 than in previous years. At the end of the statistical review the conclusion is drawn that two broad facts emerge from a study of the aggregate figures. The first is that the work of the voluntary hospitals in London is extending in consequence of their ceasing to be solely the refuge for the indigent sick, and their having responded to demands from other classes of the community for services which they alone can give. The second fact is that the receipts of the hospitals have kept pace with the increased expenditure on the whole; the increase in them indicates the quickening of public interest, and affords evidence that the basis upon which the voluntary hospitals rest is broadening. No support is therefore forthcoming for the pessimistic views expressed from time to time that the voluntary system will not be able to discharge the heavier tasks imposed upon it by changing social conditions. So far as London is concerned it appears clear that the community is ready to support in an ever-increasing measure the unique heritage of our voluntary hospital system.

Scotland.

University of Glasgow.

Sir Donald MacAlister, Bt., K.C.B., M.D., who recently resigned the post of Principal of Glasgow University after twenty-two years' service, has been elected Chancellor of the University, in succession to the late Earl of Rosebery. The appointment was made on October 30th, at the meeting of the General Council of the University.

As briefly announced last week (p. 836) the King, on the recommendation of the Secretary of State for Scotland, has been pleased to appoint Robert Sangster Rait, C.B.E., M.A., LL.D., to be Principal of the University of Glasgow in succession to Sir Donald MacAlister. The new principal was formerly professor of Scottish history and literature in the University of Glasgow and Historiographer Royal for Scotland. He was born at Aberdeen and Oxford, where he was educated at Aberdeen and graduated in 1874, and was elected to a fellowship of New College. In 1913 he was elected to the newly founded chair of Scottish history and literature at the University of Glasgow, and in 1919 became Historiographer Royal for Scotland. During the period of his connexion with Glasgow, Professor Rait has taken a prominent part in administering the affairs of the University, being for a time dean of the Faculty of Arts. During the war he served in the War Trade Intelligence Department, and for his services was created C.B.E. in 1918. He has occupied himself to a great extent not only in antiquarian research and publications with regard to Scotland, but also in military and Indian history. He has long been recognized as a popular and gifted lecturer to audiences of all kinds, and has taken great interest in the problems of university education.

General Board of Control for Scotland.

The fifteenth annual report of the General Board of Control for Scotland has just been published. At the beginning of the present year there were in Scotland 19,031 insane persons, exclusive of those maintained at home by their natural guardians, but including the inmates of training schools for imbecile children who had not been certified under the Mental Deficiency Act. Of these, 2,973 were maintained from private sources, 15,985 by parochial rates, and 73 at the expense of the State. The total number showed an increase of 329 over the figure for the previous year. The total expenditure of local authorities on the maintenance of pauper lunatics for the year ended May 15th, 1928, was £781,586, of which £667,436 was for maintenance in asylums, £38,828 for maintenance in lunatic wards of poorhouses, and £50,728 for maintenance in private dwellings. Of this expenditure £51,593 was repaid by relatives and others, so that the net expenditure by local authorities amounted to £614,260. The report comments upon several important medical points. The question of "carriers" in relation to infectious disease in asylums is mentioned. One carrier had been responsible for transmitting enteric fever to over a hundred people in widely separated parts of the country owing to frequent changes of situation, and, ultimately becoming mentally depressed, was certified. At present fifteen enteric fever carriers are under treatment in Scottish asylums, all women. The Govan District Board of Control had provided a special detached hospital for insane carriers, which was large enough to accommodate forty patients, and they were prepared to take all the carriers from other Scottish mental institutions. The undesirability of continuing the use of the term "pauper" as applied to lunacy is adverted to. The number of patients in asylums over the age of 65 was 2,964, representing approximately 23 per cent. of pauper certified patients and 16 per cent. of private certified patients in asylums. Of these elderly patients 22 per cent. were bed-ridden. The designation of "pauper" is particularly objectionable when applied to the insanities of old age, and the anomaly is pointed out that whereas an ordinary pauper is not qualified by pauperism for an old age pension, a person who has technically become a pauper as the result of insanity is disqualified from continuing to receive an old age pension. With regard to service patients, 2,074 patients who had served in the army were admitted to Scottish asylums from 1914 to 1928. Of these 650 had been discharged recovered, 320 unrecovered, and 356 had died, while the number still under treatment at the end of 1928 was 635. The Board of Control is of opinion that more extensive use should be made of the administrative facility for boarding out patients, which makes it possible for the board to remove patients from asylums to private dwellings and to transfer them if necessary back to institutions, without interference with the judicial order on which they were originally committed to asylums. Remarks are made in regard to the equipment of the ideal mental hospital, which should possess laboratories for investigation and research. In particular, the possession of an x-ray apparatus by every mental hospital with 500 beds is considered by the Board to be as necessary as it is for a general hospital. The value of installations for electrical therapy, hydrotherapy, and light therapy is commented upon.

Gift to Edinburgh University.

A sum of £30,000 has been presented by Mr. T. B. Macaulay, president of the Sun Life Assurance Company of Canada, to the Animal Breeding Research Department of Edinburgh University. Of this sum £5,000 is set apart for the purchase of a farm where the theories of the laboratory can be tested out. This supplements a gift of £30,000 previously made by Lord Woolavington towards the a gift of £10,000 by the Rockefeller Trust, and endowment of the chair of animal breeding at Edinburgh. It is expected that the genetics department, which is a unique department of Edinburgh University, will be ready for occupation early next year. It is at present under construction at the King's Buildings on the south side of the city. The work to be done will be of great importance

from the medical as well as from the agricultural point of view. The department is under the charge of Professor F. A. E. Crew, and work is especially being carried on at present along the lines of the effect which the organs of internal secretion exert on the various phases of reproduction. The department has had the co-operation of farmers and breeders throughout the country, especially in considering problems relating to sheep, and in investigations regarding the inheritance of milk yield and quality.

Correspondence.

LOCAL ORGANIZATION OF MATERNITY SERVICE.

SIR,—In February last I suggested to the executive of the Newcastle Division that it would be in the best interests of maternity in this area if a thoroughly representative committee were appointed to investigate the present system. This city contains a medical school concerned with the teaching of students and post-graduates; a maternity hospital where midwives and students are trained; health authorities, concerned with organization and administration; and doctors and midwives. All the essentials for organizing an efficient maternity service being present, it seemed desirable to have a general discussion.

The committee appointed is thoroughly representative of all these interests, and the discussions which have taken place have been most helpful. They have enabled those taking part in them to appreciate each other's difficulties and limitations. The various problems, such as nursing, the provision of dressings, and expert assistance for necessitous cases, and so on, have been dealt with in a most practical manner. The bedrock principle of the committee has been to discuss how best to make good the very obvious existing deficiencies as a preliminary to the organizing of the service as a whole. Such a committee keeps each section of the profession in touch with what is going on in other departments.

The next problem to be tackled is the relation of the local doctors to the ante-natal centres, upon which so much depends for the future of obstetrics in this area. Whatever emanates from this committee will have the hallmark of co-operative effort, and will be free from any taint of bureaucracy.

It would be sound policy if similar committees were established in other parts of the country. Even in areas without a medical school or maternity hospital it would be helpful if the doctors, health officers, and nursing supervisors met together and freely discussed the problems concerned.—I am, etc.,

E. FARQUHAR MURRAY,
M.D., F.R.C.S.

Newcastle-upon-Tyne, Oct. 30th.

POPULAR HEALTH LECTURES.

SIR,—It is credibly reported that the members of the Birmingham Insurance Committee are agreed as to the value of the health lectures to insured persons delivered under their aegis. The only criticism they put forward is that some of the lecturers have been unable to couch their utterances in sufficiently simple language, and have made too free use of technicalities. Though no evidence is produced to show the real value of these lectures, doubtless it is not fictitious, and some of the seed has fallen on good ground. If it is allowed that valuable work has already been done in spite of a certain amount of obscurity, what a field of opportunity lies in the direction of lucid, simple, and entertaining instruction.

In considering the difficulties shrouding the future of insurance practice—not the least of these being the embarrassment of the Drug Fund—one is thrown back again and again to the weapon of education. Has not the time arrived when the Minister of Health should include it as an essential part of the central administrative problem? If the education of the insured person is worth while—and the Birmingham Insurance Committee assures us that it is—then its possibilities should be exploited to the full; and no one can say what benefits might accrue to the whole insurance system. But it is of importance that health lectures should be given only by those who understand the popular need and the popular mind, who are themselves equipped with a genuine gift of expression, and are not afraid to salt their remarks with humour. There would then be no necessity, in the reported words of a member of the committee, "to point out kindly to the doctor the desirability of making his talk so simple that it would be of the greatest value to those attending."—I am, etc.,

W. A. STOKES.

West Malvern, Oct. 24th.

BACTERIOLOGY OF THE TONSILS IN RELATION TO RHEUMATISM.

SIR,—The recent investigations of Drs. Nabarro and MacDonald into this subject, as detailed in their article published on October 26th (p. 758), is a further valuable contribution to this important question. The similarity in their bacteriological findings in tonsils of rheumatic and non-rheumatic children further emphasizes the fact that the presence of pathogenic organisms, whether streptococcal or otherwise, in any possible focus of infection, does not necessarily mean that an infective rheumatic condition will result. The individual resistance to such an infective agent is apparently of greater importance than the organisms concerned in determining the commencement of a systemic infection.

In the paper "Foci and nature of infection in 100 cases of rheumatic conditions," published in the *Journal* of July 13th (p. 43), I reported that by the pathogen-selective culture method I had been able to discover the cases in which the tonsils contained an active focus of infection. From a series of 100 patients suffering from rheumatic infections I was able to make pathogen-selective cultures from the tonsils of 57, and in 41 of these (approximately 72 per cent.) was able to isolate streptococci pathogenic to the patient examined; in 20 the streptococci were haemolytic, and in 21 they were non-haemolytic. All the patients in this series were adults with a history of more or less established rheumatic infection. It would be of interest to carry out similar pathogen-selective culture examinations upon the tonsils of rheumatic children, and from my experience it seems to me that not only would it be possible to demonstrate in which of such children the tonsils were active infective foci, but also which of the streptococcal strains present was the actual infective agent in the patient concerned. Furthermore, in children showing as yet no sign of active systemic infection, the isolation of organisms pathogenic to the patient by the pathogen-selective culture method would not only incriminate the suspected tonsil, but indicate that sensitization to such an infection was taking place. Apart from the necessary removal of the infective focus, a child in this condition would require active immunization either to desensitize him or to increase his general resistance to the specific infection.

In the group of cases I have referred to it was possible to show that active pathogenic infection in adult rheumatic patients was taking place from the post-nasal space and associated sinuses in 77 per cent., from the intestinal tract in 65 per cent., from the tonsils in 63 per cent., and from the dental foci in 62 per cent. Such findings may not hold good for children, and it is likely that the pathogen-selective culture method might prove the tonsil in rheumatic children to be by far the most important focus of infection, but in any individual case the possibility of serious infection being present in the post-nasal or intestinal areas should not be forgotten or overlooked. Such omission is liable to occur, merely because both these foci are less easily observed in the child than the more obvious tonsil.—I am, etc.,

Liverpool, Oct. 30th.

TONSILS AND ADENOIDS IN HOSPITAL PRACTICE.

SIR,—In the *Journal* of October 19th (p. 736) there appear letters from Dr. C. Paget Lapage and Mr. J. Arnold Jones outlining a scheme of investigation that is being conducted at the Manchester Children's Hospital to determine whether tonsil operations in children as out-patients are attended by more accidents than those performed under more comfortable conditions.

At the London Jewish Hospital pressure on our accommodation has compelled us to undertake these operations in the out-patient department. Not feeling too sure about the environment to which these children are sent back after operation, we had inquiries made some time ago as to the home conditions of the children booked for operations, but the information elicited was sad beyond any expectation. Out of one group of forty-eight cases, no fewer than eleven were found to live in circumstances which are really appalling, as can be seen from the following summary reports.

Girl, aged 4½ years, shares bed with parents; there is one other child, they live in a box-room.
Boy, aged 12, shares bed with two sisters on top floor in small box-room.
Boy, aged 5, shares bed with his father and two brothers; three girls share the mother's bed.
Girl, aged 5½, shares bed with her parents and another child; two other children in same small room.
Girl, aged 7, shares bed with two others in parents' room.
Boy, aged 1½, shares bed with three other children in parents' room. Conditions very bad.
Two sisters, aged 4 and 5½, share single bed in small room where parents also sleep.
Boy, aged 7; three children share bed in small room. Conditions very bad.
Girl, aged 3, shares bed with two other children in same room as parents. Conditions most unhealthy.
Girl, aged 4, shares bed with three other children. Conditions very bad

This list is selected only in the sense that it represents the less favourably situated among the children awaiting operation. It is not selected to bring out the worst of that class, and is typical both in the proportions and conditions of other groups investigated. The conditions revealed, therefore, apply to approximately 25 per cent. of the children booked for operation at this hospital, and is in all probability typical of other hospitals in the East End of London. It may be that elsewhere conditions are more favourable, but personally I feel that the opponents of the propaganda in favour of in-patient treatment of these cases have much to answer for.

Unfortunately the realization that these children are best treated as in-patients does not automatically create the necessary beds. We are therefore still compelled to perform these operations in the out-patient department, and as a sop to our surgical conscience we have put the worst cases on the waiting list for in-patient admission; that list, however, is heavily overburdened, and shows but little sign of ever coming down to manngeable proportions. The truth of the matter is that it is not merely a question of there being insufficient accommodation for these cases, but that there are far too few ear, nose, and throat beds altogether. In London the beds at the special eye hospitals considerably outnumber those at the ear hospitals, being in fact, about double, though the need of the otologist is the greater. At the general hospitals the number of beds allotted to the ear surgeons is almost invariably hopelessly inadequate. It is this shortage of beds which prevents the necessary in-patient treatment of many acute ear conditions, and is directly responsible for the appalling amount of suffering from deafness and discharging ears that is present in the community. The pitiable shortage of in-patient accommodation for tonsil operations is but an exaggerated feature of the general shortage of beds for the specialty. The British Medical Association would do a great service were it to take up the larger problem.—I am, etc.,

M. Sourasky.

London, W.1, Oct. 30th.

THE CONTROL OF MEASLES.

Sir,—I should like to endorse the opinions expressed by Dr. D'Ewart (October 19th, p. 737) and Dr. Stanley Banks (November 2nd, p. 830). I feel sure that many doctors who see large numbers of these cases in general practice must have come to similar conclusions. I would go further and say that broncho-pneumonia as seen in children is not a disease *per se*, but is a manifestation of an avitaminosis (usually of the rickety type) making its appearance when an illness such as measles or whooping-cough lowers still further the already decreased natural resistance.

From the point of view of preventive medicine I think it is most important that we should consider the problem from this aspect—that is, not merely that broncho-pneumonia tends to follow rickets, but that, for all practical purposes, broncho-pneumonia *is* rickets. One does not expect a builder to be anxious because a house will have to withstand a fall of snow or a deluge of rain if he has used sound material. "One would be surprised were he to say that a building "had never been the same since that high wind two years ago."

Let us agree, then, that it is almost entirely among the "jerry-built" children that we get complications and bad health following measles. Then we may endeavour—by attending to the deficient diet and other causes of this underlying weakness—to make those children more resistant, like their more fortunate brothers and sisters who come through such illnesses unscathed.—I am, etc.,

A. Keith Gibson.

London, W.10, Nov. 3rd.

TANNIC ACID TREATMENT OF BURNS.

Sir,—The results of a questionary sent out to various hospitals and authorities have been considered by the Medical Advisory Committee of the Industrial Welfare Society. The consensus of opinion shows that, although tannic acid has been proved to be of considerable value—especially in hospitals—it should be used only under medical supervision and not as a first-aid application for burns by the general public or ambulance attendants, nor in the nursery, owing to the complicated character of the treatment and the extremely poisonous nature of the corrosive sublimate suggested to be used with the tannic acid.—I am, etc.,

D. A. Coles,
Chairman, Medical Advisory Committee of the Industrial Welfare Society.

London, S.W., Nov. 2nd.

RESPIRATORY FAILURE DUE TO CEREBRAL ABSCESS.

Sir,—In his interesting and detailed account in the *Journal* of November 2nd (p. 802) of a death from a left-sided tempero-sphenoidal abscess of otitic origin, Dr. A. Anderson stresses the manner of death—respiratory failure, sudden in origin. Having seen several of these cases in the last year I should like to point out that he has very accurately described what is the typical death. Even when the abscess is diagnosed and evacuated the difficulty of drainage, and the formation of pockets of pus, usually cause a return of the cerebral pressure and the corresponding drowsiness. When meningitic symptoms are present and lumbar puncture is performed, death seldom occurs at once; but the pressure from above sooner or later causes thrombosis or obstruction of vessels in the brain stem; the resultant oedema and respiratory failure are sudden. Death is always respiratory in type, and, when drainage of the abscess is good, it may be long delayed; occasionally recovery may ensue. It would be interesting to know the state of the patient's discs and if there was any aphasia or perseveration. To my mind the great point of interest in this case is that it is a further warning of the possibilities of grave intracranial lesions in otitic conditions without perforation of the tympanic membrane.—I am, etc.,

J. G. Kingsbury.

Sutton, Surrey, Nov. 4th.

QUININE AND BLACKWATER FEVER.

Sir,—In my book on *Blackwater Fever* I stated my opinion that this disease was due to the malignant tertian parasite, and that congestion of the liver *at the time* (as from a chill, alcohol, etc.) threw the whole work of getting rid of the debris in the blood upon the kidneys, as evidenced by the jaundice and the haemoglobinuria. Large doses of quinine may, in some people, produce haemoglobinuria, but that is not blackwater fever, with its intense jaundice, extreme weakness, and enormous spleen. Many persons have taken large doses of quinine without getting haemoglobinuria or any other symptom of blackwater fever. In districts where there are no malignant tertian parasites and where people get other forms of

malaria, and have taken large doses of quinine, how is it that blackwater fever does not develop? This variety of parasite is confined to certain highly malarious districts, and in one district I had myself to treat four successive cases of blackwater fever in one house, and there were previous cases in the same house before my time. The occurrence of an attack of blackwater fever in a person taking quinine is apt to suggest that quinine is the cause of the attack. What happens is that the individual, being unaware that he has a malignant tertian infection, either neglects to take his quinine or takes it in the small doses prescribed for prevention, until he gets a sharper attack and develops blackwater fever; or he might take a large dose, but too late to prevent the attack. An examination of his blood during the period when he was not taking quinine would have revealed the presence of the parasite, and by means of a suitable quantity of quinine the attack could have been averted. If the patient had taken doses of quinine larger than those prescribed for prevention he would not have developed the attack. The usual event, however, is that he goes about with the parasite developing in his blood and his liver already congested, and then develops a chill at the time an attack of malaria is due. The small preventive doses of 5 grains will not touch the malignant parasite. For anyone in a malarial district to take 30 to 40 grains of quinine in *one dose* is folly; whereas a brisk purge, prevention of chill, and 15 grains of quinine night and morning will probably prevent an attack of blackwater fever. It is, of course, important to know if the malignant tertian parasite does or does not exist in the vicinity. To withhold quinine in a malignant infection is asking for blackwater fever; on the other hand, if the patient has neglected to take quinine and has a highly congested liver, to prevent blackwater fever it is necessary, first of all, to relieve the latter.—I am, etc.,

A. G. NEWELL, M.D., D.P.H.

St. Leonards-on-Sea, Oct. 27th.

SIR,—The letter by Mr. Morley Roberts (October 26th, p. 787) leads me to express my views founded on some personal experience.

I believe it is held by most authorities that blackwater fever occurs as a sequel to malarial attacks which have been inadequately or ineffectively treated. I suggest that the dosage of quinine—as also the mode of its administration—has, *in itself*, but little bearing on the incidence of this complication or sequel. Although in certain cases it may have seemed evident that administration of quinine has precipitated an attack, I suggest that other factors, greater by far in importance and complexity of action, have been at work, so constituting the main cause, by which I mean the biochemical reactions of the body, and their failure to respond successfully. In this respect the term idiosyncrasy may be suitable.

During several years' tropical experience in malarial countries I have known blackwater fever occur, spasmodically, amongst individuals living under very varying conditions, from those of hardship and exposure to those of comparative ease and comfort. Again, amongst individuals, with apparently similar histories of malarial attacks, who have undergone similar routine treatment (including quinine administration of similar dosages, heroic and moderate), blackwater fever has developed in the few, but spared the majority. The disease has attacked for the first time an individual with a long malarial history, after long sojourn in the tropics, as also it has attacked another who may not have had more than one or two malarial attacks and who may have but recently arrived in the tropics.

It is seemingly a disease that awaits its opportunity, and it has attacked individuals in their homes in temperate climates, when perhaps they may have forgotten about such things as tropical ailments. From all this it would appear to me most probable that in malarial cases it is in the degree of biochemical variations away from the normal that the cause of excessive haemolysis is to be sought and found, as also the cause of failure of the body in some cases to deal with a comparatively slight haemolysis.

The above remarks amount to nothing very much more than the equivalent of a cloak to ignorance, but after a perusal of various publications from time to time, written by different authors, I conclude that the real cause of the disease is as yet obscure, as also is the reason for the apparent individual selectivity. I submit that it is to the biochemist we must look for further enlightenment. From close observation of some twelve blackwater cases during recent years it has appeared to me that symptoms and signs of liver derangement, with inflammation, have been predominating features—*ante hoc*, as well as *post hoc* and *propter hoc*. In this connexion particular interest attaches to the recent articles in the *British Medical Journal* (October 19th and 26th) on liver intoxications, and to the words "may well prove to have a wide clinical application."—I am, etc.,

L. H. BOOTH, M.R.C.S., L.R.C.P.

Sturminster-Marshall, Dorset, Oct. 30th.

TREATMENT OF INFECTIONS WITH S.U.P. 36.

SIR,—After reading Dr. J. S. Hall's interesting letter (November 2nd, p. 831) embodying somewhat far-reaching claims in favour of S.U.P. 36 in the treatment of acute infective disease, especially of acute mastoiditis, in which he says it has "proved specific," I feel compelled to plead for further details of his remarkable series of cases. Meanwhile I would utter a word of warning lest some may be led to interpret the claim of a 100 per cent. cure rate in such a treacherous and dangerous disease as an invitation to forsake the modern development of the Schwartze operation and rely on S.U.P. 36 to the exclusion of all else, in cases advanced to the degrees of empyema, abscess, or even incipient or actual intracranial complication. I feel sure that Dr. Hall did not intend the claim to be thus interpreted, his suggestion rather being to employ the remedy in the attempt to abort an attack of mastoiditis whilst the mucoperiosteum of the tympanum, antrum, and mastoid air cells, and even the bone itself, are still in a recoverable condition—a stage when surgical intervention, other than perhaps myringotomy, is not usually recommended.

I would ask Dr. Hall to let us have details of this particular series of cases, with reference especially to the type of patient, the age, the interval between the onset of the otitis media and the first injection, the signs upon which a diagnosis of acute mastoiditis was based, and lastly, but very important, whether the condition was complicating a primary acute otitis media, or occurred during one of a series of such attacks or even following a chronic otorrhoea or mastoiditis. Should the efficiency of S.U.P. 36 or any other substance be proven, then we, as otologists, must press for the still earlier recognition of the complication, and so perhaps be able to avoid the Schwartze operation altogether, not only in such cases as soon develop obvious mastoid disease, but also in those only too frequent instances of recently established chronic otorrhoea persisting in spite of adequate treatment via the meatus and to the nasopharynx and Eustachian tubes. In these cases it has been, and still is, an uphill struggle to bring the patient to the operating theatre before the hearing becomes permanently damaged or even lost.—I am, etc.,

Stoke-on-Trent, Nov. 3rd. E. HORACE RICHARDS.

THE RACIAL INCIDENCE OF DISEASE.

SIR,—If Dr. Sourasky had read with more care my letter in your issue of October 5th (p. 647) he would have seen that I argued from observations of my own on Jewish people to the established facts of biology, ethnology, and common knowledge. This is *a posteriori* not *a priori* reasoning. Moreover, I expressly claimed to make out no more than a prima facie case for my hypothesis:

> I am able, as a general practitioner, to form an approximate estimate of the proportion of Jews in my neighbourhood, as well as in my practice; and unless Dr. Sourasky is able to make some estimate of this nature in his hospital practice his impressions as to relative racial susceptibility are valueless. He would also find that

I clearly indicated that cold and damp, and not cold alone, predisposed them to infective catarrh. No better example of this could be found than present weather conditions, when a change to cold and wet, following an abnormally dry summer, heralded a widespread outbreak. Further, he would note that I did not say that Jews were not Europeans. But their advent to North-Western Europe, with its "pelagic" as distinct from "continental" climate, is recent; and their quitting of South-West Asia and adjacent regions is, biologically speaking, not remote.

Dr. Sourasky is unfortunate in selecting the Welsh, and the Italians in New York, as races which have evolved in a warm climate and migrated to a cold one. Italian emigrants are mostly from Northern Italy, where the population is of the most mixed racial origin imaginable, notable contributions having come from the north. Any "Iberian" substratum of the people of Wales came from the south when the Mediterranean climate resembled that of Britain at the present day; and it has since been interpenetrated by successive waves of "Alpine," Celt, Saxon, Norman, and other elements.

I did not say that "adenoids are all a matter of disharmony between race and climate," and must remind Dr. Sourasky that we are discussing relative frequency, not absolute incidence. I did not say that adenoids resulted from "respiratory irritation," but from catarrhal infection—a different matter; nor did I say this was the sole cause. But I do find a consensus of opinion in textbooks that infective inflammation of the nasal mucosa, including that often accompanying the exanthemata, is the paramount cause of hypertrophy of the adjacent adenoid tissue, whatever subsidiary part may be played by other conditions. The question of race and environment in pathology is not so unexplored a field as Dr. Sourasky imagines, as he will find out if he follows up the references I have given.

As regards Sir Archdall Reid's dictum (October 26th, p. 782) that "every human race is resistant to every lethal and prevalent human disease precisely in proportion to the length and severity of its past experience of that disease," I take it that he would not object to the addition of *ceteris paribus*. For we must not forget Pasteur's inability to inoculate fowls with anthrax till he kept them with their feet in cold water; nor Trudeau's experiment of inoculating rabbits with tubercle, when he found that those kept in a dark and damp cellar developed the disease and not those returned to the warren. Also non-lethal disease affecting personal attractiveness might be ultimately eliminated through sexual selection.—I am, etc.,

Hampstead, N.W.3, Nov. 1st. J. STEWART MACKINTOSH.

AN EARLY ADVOCATE OF OPEN-AIR EXERCISE.

SIR,—Dr. Jephson's name (referred to in your issue of November 2nd, p. 813) occurs frequently in letters from dwellers in Leamington between the years 1840 and 1870. He was, if not the leading, one of the leading physicians in Leamington. A letter of Sir Francis Galton to his father, Tertius Galton, on March 8th, 1844, runs as follows; I cite the whole of it as bearing on the history of medicine.

Saturday morning.

My dear Father,

As I was not able myself to enter into learned consultation with Pritchard and Dr. Jephson I cannot altogether give up my privilege of "family doctor," and so will write this letter full of prescriptions. But first I must truly congratulate you on your convalescence which Delly tells me is in capital progress, and as I presume only wanting a little hospital patient discipline to make it perfect. Now my prescriptions are:

1st. That the Hospital Patient do on no occasion feel his pulse.

2nd. That the H.P. do never look in the glass to see whether his eyes are red.

3rd. That the H.P. do never examine his own health with a view to self-doctoring.

4th. That the H.P. do make improvements at Claverdon, and commit prisoners at Leamington when so inclined, but that he never attend canal-meetings, nor put himself to inconvenience or anxiety.

5th. That the H.P. do henceforth enjoy an "otium cum dignitate" and leave hard work to younger heads for whom it is a duty.

And now my dear Father I have finished doctoring for the present, but shall go on writing doctor's letters until I hear that you obey my rules, and that you treat your own constitution with the respect it deserves for having brought you through asthma, hard work at banking and anxieties of all sorts for so long. Indeed it is a highly meritorious constitution and fairly deserves rest. I hope to be with you in about a fortnight but the exact time is not yet fixed, however I shall know before another three days, when I will write. At present I still continue full work at medicine. I am reading Hippocrates and Aretaeus in which we are examined for the M.B degree. It is now my lecture time, and so not to lose a post I send my letter unfinished but will write again on Monday.

Your very affectionate Son,

FRAS. GALTON.

Again, in the diary of Sir Francis's wife, under the year 1867 I read:

"We then went to Leamington where Dr. Jephson prescribed for Frank, he grew very weak under the treatment. End of September returned home and remained six weeks, then went to the Norths, and took lodgings at Hastings in Breeds Place; stayed there till near end of January 1867, Frank rode constantly."

Clearly, riding suited Galton better than walking, for he owed his recovery from grave illness to it. Further references to Dr. Jephson occur in Tertius Galton's diary, of which I possess a transcript.—I am, etc.,

KARL PEARSON,

November 2nd. Galton Laboratory, University of London.

SIR,—I think that there are several manuscript copies of the "Leamington Peripateticks" in existence. They were printed in the *British Medical Journal* in 1897, and again in 1911, vol. ii, p. 459. Dr. Jephson must have been very well known in his day, and probably attracted visitors to Leamington, in the Spa Garden of which there is a statue of him. A version I have seen differs in the following:

"For all the disciples who Jephson obey
Walk out in all seasons, all hours of the day."

—I am, etc.,

London, W.1, Nov. 2nd. F. PARKES WEBER.

SIR,—Dr. Jephson was one of the makers of Leamington as a spa, and the beautiful Jephson Gardens are named after him. As you suggest, he was probably a man of character, and many stories of him are told. One such relates to his method of making certain lady patients take exercise. He would take one for a drive, and then tell her to get out of the carriage to admire the view. While she was doing this he would drive away and leave the lady to get home as best she could on foot, to her great benefit, no doubt.—I am, etc.,

F. G. G.

November 3rd.

THE CONSTITUTIONAL FACTOR IN EPILEPSY.

SIR,—If Dr. Kinnier Wilson will extract an adequate and correct family history in all cases of epilepsy he will find, I believe, in about 90 per cent. clear evidence of insanity or epilepsy. A correct family history is a very difficult thing to obtain, especially in an urban population, since the majority of mankind are most reluctant to confess to this disability. Furthermore, in 75 per cent. of epileptics the first fit develops during adolescence; consequently the marriage rate is low, and the proportion of their progeny in the community is infinitesimal. Consanguinity, in two or three generations, is a recognized factor in the production of epilepsy and allied neuroses. Dr. Ryle's pertinent remarks (November 2nd, p. 830) on the constitutional factor as the predisposing cause in the incidence of this disease show a clear appreciation of this fact.—I am, etc.,

S. MCNAIR.

Oxford, Nov. 2nd.

THE BURDEN OF DEAFNESS.

SIR,—I have read Mr. Mortimer Wharry's letter in your issue of November 2nd (p. 832) with much interest. Having been deaf for many years, I can fully endorse the necessity of instruments adapted for the deaf; they are a godsend. At the same time I would like to add a few remarks to Mr. Wharry's letter. *In speaking to a deaf person* avoid shouting if possible (it is most unpleasant to a deaf person), but speak *slowly* and articulate clearly with the lips. The reason of this is that the ossicles of the ear in a deaf person do not swing or vibrate as in the normal ear, with the result that all sentences are usually heard as one continuous jumble of words. It is especially important to speak slowly when introducing new topics into the conversation, and in the pronunciation of proper names. For these reasons it is usually comparatively easy to hear and to understand barristers, clergymen, and actors. As regards privacy, I am not so sure that remarks made by pencil and paper do not come as a relief to a deaf person sometimes.—I am, etc.,

November 4th. X. Y. Z.

Obituary.

THEODORE TUFFIER, K.B.E., F.R.C.S.,

Professeur Agrégé of Surgery, University of Paris.

THEODORE TUFFIER, whose death, on October 27th, at the age of 72, was announced by us last week, was one of the most distinguished and universally esteemed French surgeons of the day. During the war he rendered conspicuous service to the French Army, in the medical organization of which he played a leading part. He was one of the first to emphasize the importance of early sterilization of wounds, and it was mainly due to his advocacy that the Carrel-Dakin treatment became generally adopted. The importance of the aeroplane in rendering rapid assistance to the wounded was illustrated by him during the French campaign in Morocco in 1920.

His services, however, were not confined to his countrymen. It was in recognition of his work for British wounded officers and men brought into Paris during the early phases of the war and of his kindly and untiring efforts to make the interallied surgical conferences a success that he received the high honour of Knight Commander of the British Empire in 1920. Tuffier's merits as a surgeon, however, had long been recognized in this country and abroad before that date. Many British and American surgeons had seen him operate in his clinic at the Hôpital de la Pitié, and later at the Hôpital Beaujon in Paris, and had come away with a pleasing impression of his skill, learning, and geniality. In 1913 he was elected an honorary Fellow of the Royal College of Surgeons of England, and two years later he received the corresponding distinction from the Royal Society of Medicine.

In addition to his services to military medicine, Tuffier's name will be remembered for having popularized spinal anaesthesia in France, and for his pioneer work in pyelography and ovarian transplantation. He held the appointment of professeur agrégé at the Paris Faculty of Medicine from 1889, and his merits in France were otherwise recognized by his election to the Académie de Médecine and the rank of Grand Officer of the Legion of Honour. The esteem in which he was held in other countries besides Great Britain is shown by the fact that he held the honorary [illegible] surgical societies of Belgium, Brazil, [illegible] Spain, Portugal, Japan, and Indo-Chi[illegible] to literature include experimental studies on the surgery of the kidney, monographs on the surgical treatment of phthisis, and articles on the urinary system in the *Traité de Chirurgie* edited by Deplay and Reclus, and on tumours of the kidney in the *Encyclopédie Française d'Urologie* in collaboration with A. Bréchot. He was also joint author of a work on minor surgery with P. Defosse, of which three editions were published.

We are indebted to Sir GEORGE MAKINS, G.C.M.G., for the following appreciation:

As senior consulting surgeon to the British Expeditionary Force in France I should like to add a word of appreciation of Professor Tuffier's services to our own army. When at the suggestion of Mr. Lloyd George the Conférence Interalliée was instituted to discuss the methods of surgical treatment in favour among surgeons of the allied armies, it was arranged that the meetings should take place in Paris, and Tuffier was elected president. He entered into the organization of these meetings with great enthusiasm. On the first occasion when the delegates arrived in Paris he was ready for us with stenographers and translators, so that the discussions on this, as on subsequent occasions, were able to be commenced at once, and be carried on with ease and precision. The conference met on four occasions, but Tuffier made an effort to keep the work alive between the official meetings by monthly gatherings at his own house. There can be no doubt that these discussions had an important influence not only in the diffusion of experience gained in the different armies, but also on methods of treatment, hospital organization, and the transport of patients. Tuffier himself was so impressed by the value of these international meetings that he made efforts that similar conferences should be continued after the cessation of the war, and in fact the fifth of such meetings was held in London this year.

During the war Tuffier visited our hospitals on many occasions, and we were always welcome at the hospitals in which he worked. He was an early and ardent adherent of the method of treatment of wounds devised by Carrel and Dakin, and speedily introduced it into the French hospitals. Whatever may be the ultimate fate of Carrel's method, it undoubtedly exerted an enormous influence on the surgery of the war. It introduced a ray of hope when surgeons were bewildered and discouraged by the results attained by other methods of wound treatment, and, although subsequent experience showed that ideal results might be gained in favourable circumstances by aseptic methods in the primary treatment of wounds, yet Carrel's or some other antiseptic method continued to be used for infected wounds, since by their means it was possible to ensure the more commonly needed secondary closure with success. Always eager to adopt new ideas, he was the first surgeon to transport a patient by aeroplane, and thus brought a man wounded in the chest from the front line over the lines of the enemy to a base hospital in North Africa.

A man of great personal charm, of high culture, a good linguist and conversationalist, he was also most hospitable. Many of my colleagues must remember with pleasure visits to his home, where he had accumulated a wonderful collection of pictures and objects of vertu of all kinds. Beyond his pleasure as a collector, I think his favourite recreations were travel and yachting. The British Government recognized his services during the war by creating him a Knight of the British Empire and a Companion of the Bath. His eminence as a surgeon had already been recognized by his colleagues by his election as an honorary Fellow of the Royal College of Surgeons of England.

Many will regret to hear of the death at Brummana, on the slopes of Mount Lebanon, of Dr. ANTONIUS JOSEPH MANASSEH, the Syrian Quaker, who received his medical education at Leeds and the London Hospital. In 1897 he obtained the diplomas L.R.C.P., M.R.C.S., and the M.D. degree of Constantinople. The influence of Friends in Leeds led him, though reared in the Greek Orthodox Church, to offer himself to the Friends Foreign Mission Association in the same year. The rest of his life, except during the war years, when he was taken into the Turkish Army as medical officer, he spent as superintendent of the Friends' medical work at Brummana. When the members of the Turkish Army were made prisoners he was speedily released by the British and appointed a prison doctor; afterwards, despite ill health, he worked with the Syrian and Palestine Relief Fund. Next to his medical work for the people of the Lebanon, which often involved long and tiring journeys on horseback, his great interest was in

his activities as a Quaker preacher and as a "bridge" between individuals and peoples who misunderstood one another. He had many opportunities for such work, not only among the rival factions of his own country, but from the fact that visitors of many lands came to the cool heights of Lebanon from all parts of the Eastern Mediterranean during the summer. Dr. Manasseh established at Brummana an international reading room and library, and from the trustees of the fund left by Robert Arthington of Leeds he obtained money for a special building for this small but important cosmopolitan centre. He took special interest in tuberculosis, and wrote a book on its treatment. He was a member of the British Medical Association.

We regret to record the death, in his eightieth year, of Dr. Matthew William Gairdner, which took place at Cheltenham on October 11th. The second son of Dr. Matthew Baillie Gairdner of Crieff, he entered Edinburgh University as a student in 1867, was a medallist in anatomy, and a dresser under Lord Lister. After graduating at Edinburgh and obtaining the L.R.C.S.Ed. diploma in 1871, he was successively house-surgeon at Chalmers Hospital to Mr. Annandale, house-physician to Dr. George Balfour, house-physician to the Hospital for Women, Soho Square, London, and assistant physician to the Montrose Royal Asylum. Dr. Gairdner thus in his medical career bridged the whole period of the genesis and development of modern surgery. In 1875 he was appointed as surgeon in the railway service in India, and later settled in Naples as the English physician. He stayed in Naples for the remainder of his professional life, and while there received the thanks of the Italian Government for his work during the severe cholera epidemic, which carried off a third of the population of Naples. Since 1910 he had lived in retirement at Cheltenham. A note in our Scottish column on September 29th, 1928, under the heading "A Medical Family," recorded the interesting fact that the professional practice of Dr. Gairdner's father and of his brother, Dr. James Gairdner, had covered more than a century. His son, Mr. Alan C. Gairdner, F.R.C.S., is on the resident staff of the London Hospital.

We regret to record the sudden death, at the age of 48, of Mr. Harry Morgan Gilmour, which took place on October 29th at his home in Ipswich. Mr. Gilmour received his medical education at St. Thomas's Hospital, and in 1903 obtained the diplomas of M.R.C.S. and L.R.C.P. After holding the post of house-surgeon to Bridgnorth and South Shropshire Infirmary he started practice at Andover, but shortly after went to Hornsey, and undertook post-graduate study at the Central London Ophthalmic Hospital. Throughout his professional career Mr. Gilmour was specially interested in ophthalmic surgery, and he held posts as ophthalmic surgeon to the East Suffolk and Ipswich Hospital, to the Harwich and Dovercourt Hospital, and to St. Audry's Hospital, Melton. He was a member of the Ophthalmological Society of the United Kingdom. In 1914 he joined the R.A.M.C. and saw active service at Loos, and, later, in Russia. Demobilized with the rank of captain he settled in practice in Ipswich, specializing in ophthalmic surgery. Mr. Gilmour was an active member of the British Medical Association, and for some time served on the Executive Committee of the South Suffolk Division. He was married as recently as last December.

The following well-known foreign medical men have recently died: Dr. Vittorio Grazzi of Florence, formerly professor of oto-rhino-laryngology at Pisa and founder and editor of *Bollettino delle Malattie dell' orecchio, gola e naso*, aged 80; Dr. Oscar Mercier, professor of clinical surgery at Montreal; Dr. José Pereira Rego Filho, for twenty-one years president of the Academy of Medicine of Rio de Janeiro, aged 84; Professor G. Uchermann, founder and president of the Norwegian Oto-rhino-laryngological Society; Dr. Ferruccio Putelli, an eminent otologist of Venice; Professor J. J. Burdakh, a bacteriologist of Odessa, aged 73; Dr. Ott, a gynaecologist of Leningrad; Dr. Richard Zsigmondy, professor of inorganic chemistry at Göttingen and Nobel prizeman for chemistry in 1926, aged 64; Dr. André Pierre Marie of the Institut Pasteur, Paris, son of Professor Pierre Marie, from accidental inoculation of botulism, aged 38; Dr. Adelward, formerly physician to the Empress Eugénie and a companion of Livingstone, aged 102; Dr. Charles van Niewenhuyse, an eminent Brussels paediatrist; and Dr. Morton Prince, emeritus professor of neurology at Tuft's College, associate professor of abnormal psychology at Harvard University, and editor of the *Journal of Abnormal Psychology*, aged 74.

Medical Notes in Parliament.

[From our Parliamentary Correspondent.]

The House of Commons this week heard from Mr. MacDonald a statement on his visit to the United States and Canada, and one from Mr. J. H. Thomas regarding schemes for increasing employment. The House, after a debate and a division, approved the draft treaty made by Mr. Henderson with Russia. The Viceroy of India's recent declaration on the future government of India was discussed in both Houses. The President of the Board of Trade announced his decision to set up next year a Consumers' Council with compulsory powers.

Widows', Orphans', and Old Age Contributory Pensions Bill.

In moving the second reading of this bill, on October 31st, Mr. Greenwood alluded to the general survey of national insurance and pensions schemes which the Government had undertaken. He said there were important differences in scope between the national health and the unemployment-insurance schemes, but the closest touch between the two departments concerned. On questions of insurability there was a joint administration. As a consequence of the system growing up piecemeal they had distinct forms of administrative machinery for services broadly similar in purpose. A committee of the Cabinet was now surveying the various schemes, their gaps, inadequacies, and overlapping, and also the relations between insurance and various forms of social service outside insurance. The recommendations of the Royal Commission on National Health Insurance and the recent report from the Departmental Committee on the Training of Midwives both pointed to an extension of the services under the National Health Insurance Acts. Among the possible extensions which the Government had to consider were the provision of medical and midwifery services during pregnancy and childbirth to insured women and wives of insured men; the extension of medical benefit to include specialist and consultative medical service, laboratory aids to diagnosis, and the possibility of making dental benefits statutory. Mr. Greenwood then went on to expound the bill before the House. He remarked that many people who had suffered through long unemployment knew that their insurance would terminate on December 31st, 1929, because of the repeal of the Prolongation of Insurance Act. He proposed to make transitional arrangements to keep such persons in insurance until December 31st, 1930. They would retain their title to sickness, disablement, and medical benefit, and would keep alive their insurance for pensions. He proposed to issue regulations to ease the difficulties.

Mr. Carter referred to the Minister's intention of extending the period for elderly contributors who had failed to secure the requisite contributions in the last three years. He welcomed the proposal because it would reduce the power of the medical profession with regard to this class of person. At present it practically rested with the medical profession to decide whether an insured person in certain circumstances got what was called a redeemed stamp. He cited a case where the doctor had been "able to stop" a man getting his pension, so that the man had lost not only his pension but sick pay. Mr. Carter said that the taking away of this power from the doctor was a matter for congratulation. He added that he was not the only one to draw notice to the inattention of the medical profession to the panel patients. Dr. Edwin Smith, coroner in the East End of London, had publicly called attention to these cases where they had come before him.

After further debate the bill was read a second time without a division and sent to committee of the whole House.

On November 1st a financial resolution, authorizing expenditure on the same bill, was proposed by Miss Susan Lawrence, and was carried by 206 to 64. During the debate on this resolution Dr. Fremantle said he had tried in the House to speak for the medical profession and ancillary professions. No body of men became so intimately acquainted with the material condition of people of every class, and therefore his profession had a keen interest in measures such as that before the House. Throughout that profession there was an immense amount of support for any measure which tried to mitigate the hardships in the poor homes of this country. But, as the Chancellor of the Exchequer had said, there must be a limit to this kind of expenditure. The main provision of this country for the relief of distress and need was the Poor Law, now transferred to new and larger authorities; this intimate system provided by the guardians ought to be the best for others who needed help as much as the widows to be aided under the bill.

House Shortage and Unemployment.

On November 4th Mr. J. H. Thomas made a statement as to his plans for dealing with unemployment. During the debate which followed, Sir R. Aske urged that something should be done to deal with unemployment in the building and allied trades, which represented 12 per cent. of the whole problem. There was an amount of frightful overcrowding in all the great industrial centres. This had a very bad effect on the health of the people. Mr. Thomas, intervening, said that one of the first measures of the Government this session would be a slum clearance bill to deal with one side of the housing problem. He had urged the municipalities to take advantage of the Government's facilities to help them to undertake work which ought to have been done long ago. That offer was still open. Sir R. Aske said that slum clearance would not meet the difficulty. There was an actual shortage of houses, and they must build houses before they destroyed the slums. The health of the people was suffering, and if the Government did not build the houses now they would have to build hospitals in the future.

Enteric Fever in London.

Mr. Greenwood stated, on November 1st, that from June 30th to October 26th 187 cases of typhoid and paratyphoid were notified in the county of London, and 18 deaths of London residents occurred from these diseases in London or in metropolitan institutions. In the week ended October 12th there were 23 cases and one death; in that ended October 19th 30 cases and 3 deaths; and in that ended October 26th 41 cases and 3 deaths. Mr. Greenwood explained that an outbreak in South-East London was responsible for the increase of notifications in October. Officers of the Ministry of Health had collaborated with the medical officers of health of the districts affected. The source of the outbreak had not been definitely traced, but there was reason to believe that the infection was no longer operative.

Bills.

Measures introduced in the House of Commons on November 1st after the private members ballot include a bill to amend the Shop Acts (Mr. Frederick Hall); Coal Mines (Washing and Drying Accommodation) Bill (Mr. John); Blind Persons Bill (Mr. Groves); Offices Regulation Bill (Mr. Romeril); Slaughter of Animals Bill (Colonel Moore); and a Midwifery, Maternity, and Child Welfare Bill (Mr. Alpass). The last is so far down the list that it does not appear likely to be discussed unless the Government takes it up. Its purpose is set out as "to consolidate and amend enactments relati nity (including expectant and nursing births, child welfare, maternity homes, and to make further provision with respect thereto, and to amend the National Health Insurance Act, 1924, and the Local Government Act, 1929, and to provide for the notification of certain diseases, and for the holding of inquests in certain cases, and for purposes connected with the matters aforesaid."

On November 4th Sir R. Gower presented a bill to prohibit the vivisection of dogs, which was read the first time.

Silicosis.—Replying to Mr. Hollins, on October 31st, Mr. Clynes said he was anxious to provide for partial disablement cases from silicosis, but adequate medical arrangements must first be made. The question was difficult, and had been investigated by a departmental committee, whose report had been laid before Parliament. He concurred generally in the recommendations, but they could not be given effect without further legislation. He was considering an amending bill, to be introduced and passed this session. He had no complete figures of the number of cases of silicosis among pottery workers. The departmental committee of 1927–28 recommended additional precautions, including periodic medical examinations in some of the most dangerous processes. He did not think there was any need for the appointment of any further committee.

Birth Control.—Replying to Mr. Thurtle, on October 31st, Mr. Greenwood said he did not propose to depart from previous policy and permit local authorities to give birth control information to married women desiring it.

Medical Councillors and their Pul . . . . . Davies asked Mr. Greenwood, on means by which the professional s and public vaccinators who were a borough members could be retained without forfeiture of their appointments. Mr. Greenwood replied that the report of the Royal Commission on Local Government would be out shortly, and any recommendation on this subject would be considered.

India: Central Medical Research Institute.—Mr. Wedgwood Benn, replying to Major Pole on October 31st, said that the work of the India Central Medical Research Institute had not been started at Dehra Dun up to September 2nd. Major Pole further asked whether, in view of the objection by the all-India medical associations, the Government would reconsider the decision to remove the institute to Dehra Dun. Mr. Benn promised to bring this suggestion to the notice of the Government of India, which, he understood, had already received similar representations from one or more medical associations in India.

Hop-pickers: Sanitary and Sleeping Accommodation.—Mr. Greenwood, replying to Mr. Oliver Baldwin on October 31st, said that local authorities had generally exercised their powers of making by-laws requiring farmers to notify the reception of hop-pickers. Thus the authorities were able to see that the regulations regarding sanitary and sleeping accommodation were observed. He was not aware of any need to strengthen the legal position of the authorities.

Experiments on Animals.—Replying to Mr. Freeman, on October 31st, Mr. Clynes said that the increase of experiments on living animals without anaesthetics during 1928 was largely due to the need for standardizing drugs for use in medical practice, of diagnosing the diseases of patients under treatment, and of testing the purity of milk and other foods. The report of 1912 of the Royal Commission on Vivisection made full investigation of the whole question of experiments on animals, and he thought no further inquiry was necessary.

Tannic Acid for Burns.—Replying to Dr. Vernon Davies, on October 31st, Mr. Clynes said the report of the Medical Research Council had demonstrated the hospital use of tannic acid for burns, but its first-aid use in factories had not been fully explored. The senior medical inspector of factories had been asked to go into this, and the matter would be considered on his report.

Inspection of Prisons.—On October 31st Mr. Lovat Fraser asked the Home Secretary whether, as there were no women on the Prison Commission, he would appoint an adequate quota of women commissioners and a sufficient number of women inspectors of prisons for the inspection of women's prisons. Mr. Clynes replied that no appointment of a women commissioner or inspector of prisons had been made as women now constituted only about 7 per cent. of the prison population, the daily average having fallen from 1,604 in 1919 to 804 in 1928.

Capital Punishment.—A motion by Mr. W. J. Brown advocating the abolition of capital punishment was discussed in the House of Commons on October 30th. Sir Herbert Samuel moved an amendment in favour of the appointment of a select committee to consider the question. After debate, Mr. Brown accepted this amendment, which was carried by the House. Mr. Clynes said that the Government would be disposed to act upon what report such a select committee might submit.

Battersea Power Station.—To take precautions for the consumption of smoke and to prevent, as far as reasonably practicable, the evolution of oxides of sulphur, the London Power Company, which has been authorized to construct the first section of the Battersea power station, has been conducting experiments. An interim report from the Government chemist on these experiments is under consideration by the Ministry of Transport.

Protection against Chemical Warfare.—On November 5th Mr. Shaw told Mr. Graham White and Rear-Admiral Beamish that research work on protection against chemical warfare was being carried out at both Porton and Sutton Oak, and he was advised that it was necessary to continue this defensive research work.

Notes in Brief.

Mr. Clynes stated, on October 31st, that eight firms were licensed to make medicinal opium, heroin, cocaine, and morphine—five for medicinal opium; one for medicinal opium, morphine, and heroin; one for morphine, heroin, and cocaine; and one for cocaine only. He could not state the capital involved or the number of persons employed, but the latter was under fifty.

Mr. Greenwood states that, from April 1st, county councils will, under Section 14 of the Local Government Act, 1929, be empowered to provide all necessary hospital treatment for orthopaedic patients.

Blind persons desiring to avail themselves of cheap travelling facilities can obtain qualifying certificates on application, either personally or in writing, to any of the whole-time offices of the Ministry of Pensions.

During the six months ended November 1st, twelve outbreaks of foot-and-mouth disease had been confirmed. In nine cases the total stock on the farms was slaughtered, and in three cases a portion was killed.

A draft report on river pollution will be circulated during this week to members of the Standing Committee on that subject for their consideration. The report will be published after its approval by the committee.

The Services.

NO. 14 STATIONARY HOSPITAL.

The tenth annual dinner of the medical officers of No. 14 Stationary Hospital will be held on Friday, December 6th, at the Trocadero Restaurant, Piccadilly, at 7.15 for 7.45 p.m. Colonel C. R. Evans, D.S.O., will be in the chair. The price of the dinner will be 15s. (exclusive of wines). Dr. H. Letheby Tidy, 39, Devonshire Place, W.1, is acting again as honorary secretary.

QUEEN ALEXANDRA'S HOSPITAL FOR OFFICERS.

The tenth annual reunion dinner of Queen Alexandra's Hospital for Officers was held, on October 31st, at the Hotel Cecil, under the chairmanship of Major W. B. Binnie, F.R.I.B.A., a former patient of the hospital. Mr. Herbert Paterson read a message from H.R.H. Princess Victoria: "I hope most sincerely that former patients and staff will spend a happy time in renewing old friendships. I send my best wishes to you all." Lord Waring proposed the health of the former patients, and Colonel F. R. Hybart, the senior officer, replied.

TERRITORIAL DECORATION.

The King has conferred the Territorial Decoration upon Lieut.-Colonel Frederick Searle, *M.C.* (employed Cambridge University Contingent, Senior Division, Officers' Training Corps).

Universities and Colleges.

UNIVERSITY OF OXFORD.

The following awards have been announced: Welsh Prize, Arnold Peter Meiklejohn; Theodore Williams Scholarship in Human Anatomy, Allan Henderson Hunt; Theodore Williams Scholarship in Physiology, Jack Watson Litchfield; Theodore Williams Scholarship in Pathology, John Rennie Braybrooks; Radcliffe Scholarship in Pharmacology, John Rennie Braybrooks and Guy Spencer Grist (equal).

UNIVERSITY OF CAMBRIDGE.

At a congregation held on November 2nd the following medical degrees were conferred:

M.D.—T. A. Butcher.
M.Chir.—J. Gray.
M.B., B.Chir.—J. St.C. Elkington, R. A. P. Gray, A. Maberly, S. S. Chesser, J. F. Stent.
M.B.—S. D. Isaacs.
B.Chir.—A. T. Howell, C. E. Donaldson.

UNIVERSITY OF LONDON.

The Senate, with the concurrence of the Court, has appointed Dr. Edwin Deller, previously Academic Registrar in the University, to the post of Principal of the University of London as from October 1st, 1929, in succession to Dr. T. Franklin Sibly, now Vice-Chancellor of the University of Reading.

UNIVERSITY OF BELFAST.

At a meeting of Convocation of the Queen's University, Belfast, held on October 29th, for the purpose of electing eight members of the Senate, four of the vacancies were filled by the election of the following members of the medical profession: A. B. Mitchell, O.B.E., M.B., F.R.C.S.I., J. S. Morrant, O.B.E., B.A., M.D., R. W. Leslie, M.D., LL.D., and Foster Coates, B.A., M.D.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

An ordinary comitia of the Royal College of Physicians of London was held on October 31st, when the President, Sir John Rose Bradford, was in the chair.

Appointments.

Dr. John Hay, Dr. F. E. Fremantle, and Dr. J. B. Leathes were elected Councillors.

The following Fellows were re-elected to various offices: Sir Francis Champneys, a representative of the College on the Central Midwives Board; Dr. H. L. Tidy, a member of the Committee of Management; Dr. J. H. Abram, a representative on the Court of Governors of the University of Birmingham; and Dr. A. S. Woodwark a representative on the Central Council for District Nursing.

Dr. Robert Hutchison and Dr. James Collier were appointed members of the Mackenzie Mackinnon Research Fund Committee.

The President announced that the Council had appointed Surgeon Commander Sheldon Francis Dudley, O.B.E., R.N., to be Milroy Lecturer for 1931, and that the Jenks Memorial Scholarship for 1929 had been awarded to Francis Sansome Mitchell Heggs.

Report.

A report was received from Dr. F. E. Fremantle, who represented the College at the fourth Imperial Social Hygiene Congress, and a communication was received from the University of Wales announcing that its advisory Board of Medicine had been recently dissolved.

Membership.

Having satisfied the Censors' Board, the following were admitted Members:

Ilahi Bakhsh, M.B.Lond., Thomas Henry Booth Bedford, M.B.Leeds, Howard [illegible], Philip E[illegible], Leslie W[illegible], watersram[illegible], Sinclair [illegible], M.B.Lond.

Licences.

Licences to practise physic were granted to the following 126 candidates (117 men and 9 women), who have passed the final examination of the Conjoint Board in Medicine, Surgery, and Midwifery, and have complied with the by-laws of the College:

H. S. Atkinson, G. O. Barber, B. E. Barnett, G. H. Bateman, T. S. Belcher, F. Bell, E. Tellamy, J. H. Bentley, J. A. K. Brown, W. D. [illegible], D. R. Buchan, P. C. [illegible], S. C. S. Cooke, W. H. [illegible], C. P. P. [illegible], I. G[illegible], I. [illegible], I. [illegible], E. N[illegible], [illegible], E. [illegible], J. [illegible], H. R. Hodson, J. Hopton, R. H. Hucknall, Marr A. Hughes, E. E. Hunt, C. S. Kah, K. S. Keele, E. J. Kerr, H. Y. Khwaja, R. Kramer, M. Lee, E. C. Lewis, W. D. Lovelock-Jones, F. T. F. Lutter, R. W. McConnel, D. M. MacLachlan, F. N. Marshall, Eileen M. Massey, N. D. Matson, D. C. W. Maxwell, P. H. Merlin, T. J. Millin, C. W. Morley, I. B. Morris, D. P. F. Mulvany, W. D. Neill, J. N. O'Reilly, R. W. Paine, D. H. Parkinson, L. H. Peiris, J. Petro, I. D. Phelps, R. F. A. Phil[illegible], A. C. Price, N. L. Price, S. [illegible], Quick, J. P. Rabau, B. B[illegible], J. A. Rogers, T. N. Rudd, [illegible], D. Sheehan, B. C. Singh, J. O. Smith, A. Somervi[illegible], J. D. S. Stephens, T. Stephens, M. Sternfeld, Muriel H. Steven, G. D. Stilwell, B. J. Stracey, B. D. Tanoja, J. M. Taylor, T. B. E. Taylor-Jones, E. G. Thomas, J. C. T. Tregarthen, C. E. H. Turner, G. S. Walker, C. J. Waring, J. B. Watkin, E. Watman, V. W. L. Wells, T. H. N. Whitehurst, T. H. Wilson.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

At the monthly business meeting of the College, held on November 1st, the following successful candidates at recent examinations were duly admitted: Membership, V. Nath, L.R.C.P.and S.Edin., L.R.F.P.and S.Glas.; Licence in Midwifery, B. T. Chua, L. Yang.

The following resolution was passed in silence, all present standing:

That we, the President and Fellows of the Royal College of [illegible] with profound regret of the death [illegible] of the College, for whom we all [illegible] affection. We feel that both this [illegible] in Ireland have sustained a great [illegible] re to convey to his relatives this [illegible]

SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have been approved in the subject indicated:

Surgery.—A. Buch, B. F. M. Child, W. J. H. Coidan, R. W. Goldsbrough, A. Guirdham, H. C. Haige, G. A. F. Holloway, A. Kellner, R. K. Nandial.

Medicine.—W. T. Ellis, W. J. Frith, A. Guirdham, W. M. Hamer, W. St. A. Hendricks, R. J. Kagan, H. W. Maurer, T. M. White, F. A. Yarde.

Forensic Medicine.—A. N. De Monte, W. J. Frith, B. C. Ghose, B. Gilmore, A. Guirdham, W. St. A. Hendricks, G. A. F. Holloway, C. Horton, A. D. H. Hugo, A. Liberis, W. McDermott, J. E. Moody, L. J. Pearson, T. G. Robinson, L. C. H. Sykes, F. A. Yarde.

Midwifery.—M. Asaad, B. F. M. Child, A. Clark, C. E. P. Davies, A. N. De Monte, H. R. Fosbery, A. Guirdham, J. E. R. Hempolette, G. A. F. Holloway, D. W. Hoskins, V. J. Lopez, W. McDermott, L. J. Pearson, S. Ramadas.

The diploma of the Society has been granted to Messrs. A. Clark, A. N. De Monte, W. T. Ellis, R. W. Goldsbrough, A. Guirdham, W. M. Hamer, W. St. A. Hendricks, G. A. F. Holloway, C. Horton, W. McDermott, and T. M. White.

Medical News.

"Medical research: the tree and the fruit," is the title of the Norman Lockyer Lecture to be given at 4.30 p.m. on November 19th by Sir Walter Fletcher, K.B.E., C.B., M.D., F.R.S., in the Goldsmiths' Hall, Foster Lane, E.C. Lord Melchett will preside. Tickets of admission (free) may be obtained on application to the Secretary, British Science Guild, 6, John Street, Adelphi, W.C.2.

The annual dinner of the Society of Medical Officers of Health will be held at the Piccadilly Hotel, W., on Thursday, November 14th, at 7.30 p.m.; reception at 7.10. The Government will be represented, and among those who have accepted invitations are Sir Arthur Robinson, Sir George Newman, Sir John Rose Bradford, P.R.C.P., Lieut.-General H. B. Fawcus (Director-General A.M.S.), and Surgeon Vice-Admiral A. Gaskell (Director-General, Medical Department, R.N.). Tickets are obtainable from the executive secretary at 1, Upper Montague Street, Russell Square, W.C.1. A payment of 12s. 6d. for each ticket should be made with applications sent before November 11th; after that date the cost will be 15s. each.

The seventh Lloyd Roberts Lecture will be delivered at the Royal College of Physicians of London, Pall Mall East, by the Right Hon. A. L. Fisher, LL.D., F.R.S., on Thursday, November 14th, at 5 p.m.; the subject is "An Oxford movement."

The Hunterian Society of London will hold a discussion on "The doctor and the motorist" at 9 p.m. on Monday, November 18th, in the Cutlers' Hall, Warwick Lane, E.C. The speakers will include Earl Howe, Mr. E. B. Turner, and Dr. P. B. Spurgin.

The Cambridge Graduates' Club of St. Bartholomew's Hospital will hold its fifty-third anniversary dinner on November 20th, at 7.30 p.m., at the May Fair Hotel, with Dr. H. Morley Fletcher in the chair.

A meeting of the Biochemical Society will be held in the Department of Physiology of the University of Liverpool to-day (Saturday, November 9th) at 2.30 p.m., when papers will be read, and demonstrations given during the tea interval.

THE next meeting of the Oxford Ophthalmological Congress will be held in 1930, on *July 10th*, 11th, and 12th. The honorary secretary is Mr. C. G. Russ Wood, 12, St. John's Hill, Shrewsbury.

UNDER the auspices of the Fellowship of Medicine a lecture, free to medical practitioners, will be given at the Medical Society lecture room, 11, Chandos Street, Cavendish Square, on Monday, November 11th, at 5 p.m., by Dr. E. P. Poulton, on the treatment of the common cold, and some recent work on Bright's disease. On Tuesday evening, November 12th, at 8.30, Dr. O. L. V. de Wesselow will lecture on diabetes and insulin; and on Friday, November 15th, at 8.30, Dr. Bernard Myers will discuss purpura and its treatment; these two lectures are especially suitable for M.R.C.P. candidates. A demonstration of gynaecological cases will be given at Charing Cross Hospital by Dr. Everard Williams at 2 o'clock on November 13th, and a demonstration of genito-urinary cases and cystoscopic examinations will be given at St. Paul's Hospital, Endell Street, from 4.30 to 7.30, on November 15th, by Mr. W. K. Irwin; these demonstrations are free to medical practitioners. From November 18th to 30th an all-day course in orthopaedics will be held at the Royal National Orthopaedic Hospital, consisting of in- and out-patient demonstrations, operations, lectures, and special visits to the country hospital at Brockley Hill; since a minimum of ten entries is required, early application is recommended. From November 18th to December 13th the West End Hospital for Nervous Diseases will hold a course in neurology consisting of daily lectures and clinical demonstrations, at 5 p.m. From November 25th to 30th there will be an all-day course in proctology at St. Mark's Hospital. In December there will be courses in infants' diseases and dermatology, and a practitioners' course in medicine and surgery will be held, occupying one and a half hours daily. Copies of all syllabuses and particulars of general work may be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

THE University of Birmingham Dental Clinical Board announce that four post-graduate lectures will be delivered at the Dental Hospital, Great Charles Street, Birmingham, on Thursdays, at 5 p.m.: November 14th, fractures of the jaws, by Mr. Harold Round; November 28th, diagnosis and prognosis in dental practice, by Colonel W. Bowater; December 5th, surgical removal of teeth, by Mr. H. S. Swann; December 12th, preparation of the mouth for dentures, by Mr. S. H. Roe. The fee for the course is one guinea, which should be sent to the clerk of the Dental Clinical Board, University, Edmund Street, Birmingham, or to the Dean of the Dental Hospital, Great Charles Street, Birmingham. Tea will be provided at 4.30 p.m. at the hospital.

THE *foundation stone of the new Queen Charlotte's* Maternity Hospital at Hammersmith was laid by Princess Marie Louise on November 4th. The hospital when completed will consist of 353 beds, and will be the largest maternity hospital in the British Empire. The stone was *laid in the isolation block*, which is to be built first, for the reception of cases of puerperal fever and the carrying out of *laboratory investigations into the origin of the disease.*

DR. H. E. KING REYNOLDS, secretary of the York Panel Committee and assistant secretary of the York Division of the British Medical Association, has been elected a member of the York City Council.

SIR ARTHUR KEITH contributes to the *Rationalist Review* for 1930 a paper under the heading "Darwin remembered," in which he tells the story of the acquisition of Down House —Charles Darwin's home in Kent—by Mr. George Buckston Browne, F.R.C.S., and its *formal handing over last summer* into the custody of the British Association. *An account of* the ceremony appeared in our issue of *June 15th (p. 1086).* The text of Sir Arthur Keith's address on that memorable occasion is now printed verbatim for the first time.

SIR THOMAS LEGGE'S Shaw *Lectures* on "Thirty years' experience of *industrial maladies*," of which an abstract appeared *in our issue of March 9th, 1929* (p. 467), have now been published in *pamphlet form* by the Royal Society of Arts, John Street, Adelphi, W.C.2, *price* 2s. 6d.

THE KING has granted Dr. John Archibald Taylor, Director of Medical and Sanitary Services and Member of the Legislative Council, Zanzibar, permission to wear the insignia of the third class of the Order of the Brilliant Star of Zanzibar conferred upon him in recognition of valuable services.

THE recent epidemic of enteric fever in South-East London has, so far as Lewisham is concerned, remained limited to the Sydenham district of the borough. The clinical features of the disease do not call for special comment. Many of the cases are of a moderately severe type, but, as only six deaths have occurred among 91 cases, the mortality at present is not above the average.

THE KING has approved of the appointment of Dr. James Cran, O.B.E., V.D., to be an unofficial member of the Legislative Council of the colony of British Honduras.

THE Lord Lieutenant of the County of the City of Glasgow has appointed Dr. Donald J. Mackintosh, C.B., M.V.O., medical superintendent of the Western Infirmary, Glasgow, to be Deputy Lieutenant.

A POST-GRADUATE course in neurology and psychiatry will be held in English in Vienna from January 2nd to February 15th, 1930, under the auspices of the American Medical Association of Vienna. In addition to covering the whole field of neurology and psychiatry, and associated branches, such as ophthalmology, the course will allow time for individual study and special classes. *Further information* can be obtained from Dr. E. Spiegel, Falkestrasse 3, Vienna I.

THE fifth international congress for physical therapy, like the first held in 1905, will take place at Liège next year. Further information can be obtained from the general secretary, Dr. Dubois-Trépagne, 25, Rue Louvreux, Liège.

A SPECIAL report on the thirteenth International Ophthalmological Congress, which was held at Scheveningen, Holland, in September, has been prepared by Mr. H. B. Stallard, and published as a supplement to the *British Journal of Ophthalmology*. Previous reference was made to this congress in our issue of July 13th (*p. 80*).

THE Lithuanian Government has approved *the project* for the *construction of an up-to-date clinic connected with* the University of Lithuania for the treatment of diseases of the eye, ear, nose, and throat. A site has been selected in the neighbourhood of the military hospital, comprising an area of 4,000 square metres. The clinic will have *50 beds for eye cases and 30 to 36 beds for ear, nose, and throat cases.* It is hoped that the clinic will be open by *October, 1930. A leading part in this undertaking* has been taken by Professor Radzvickas, who has had thirty years' experience of ear, nose, and throat cases in Russia.

THE annual report of the National Physical Laboratory for 1928 has been issued in two forms; complete in a single volume, and as the following series of separate pamphlets: the units and standards of measurement employed at the National Physical Laboratory (1s.); report on the Physics Department (1s. 9d.); report on the Electricity Department (3s.); report on the Meteorology Department (2s.); report on the Engineering Department (1s. 9d.); report on the Aerodynamics Department (1s. 6d.); *report on the Metallurgy* Department (1s. 6d.); report of the Advisory Committee for the William Froude National Tank (4d.). We have received a copy of the first of the above-mentioned pamphlets, in which an attempt is made to give clear and precise definitions of the units of *measurement, international and British* Imperial, employed at the National Physical Laboratory, with information about the *primary standards preserved and* maintained at the laboratory to represent these units.

THE report of the proceedings of the fifth English-speaking conference on maternity and child welfare which was held in London in July last has now been published by the National Association for the Prevention of Infant Mortality. An account of this conference appeared in the *Journal* on July 13th (*p. 58*), and it may be recalled that the principal topics considered were: maternal morbidity, with special reference to maternity nursing and abortion; *deformities in young* children; the psychological welfare of children; and venereal diseases in connexion with maternity and child welfare. The price of the book is 2s. 6d.; it can be obtained from the offices of the National Association, 117, Piccadilly, W.1.

ON the occasion of *his 80th birthday* the Soviet Government has presented 10,000 roubles to Professor Ivan Pavlov for *improvements in his laboratory* in Leningrad.

THE Advisory Committee on the Welfare of the Blind *proposes to arrange* correspondence courses for the education of adult blind persons in such subjects as English composition and literature, business correspondence, history, French, German, Latin, industrial history, and the theory of music. It is not anticipated that the blind will be involved in any expense in connexion with the courses, and those interested are invited to send in their names at once to the secretary of the voluntary association to which they are attached, or to their home visitor.

THE board of the Royal Northern Hospital, Holloway, and the council of the Maternity Nursing Association have agreed to *co-operate still* more closely, with a view to facilitating the nursing of mothers in their homes in Finsbury, St. Pancras, and Islington, and to promoting the training of midwives. The work will be carried on as hitherto at the Association's centres in Myddleton Square, Finsbury, and Oakley Square, St. Pancras, in addition to the hospital.

THE number of persons suffering from trachoma in Siberia has increased from 50,000 in 1924 to 80,856 in 1926, and continues to rise.

A MONUMENT to the neurologist Professor Grasset was unveiled on the occasion of the recent twentieth French Congress of Medicine held at Montpellier.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9961, 9962, 9963,* and *9964* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR of the *British Medical Journal, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

HOT FEET AT NIGHT.

"MEDICAL WOMAN," in reply to the inquiry under this heading (October 19th, p. 744), writes: The bedclothes should not be tucked in at the foot of the bed, but placed flush with it, thus ensuring ventilation at the foot as well as at the head of the bed. One of the blankets should be placed across the bed, instead of lengthways, so that there is one layer less of blanket over the legs and feet than over the rest of the body. If necessary, the bedclothes may be raised off the feet by means of a cradle. A stone jar filled with cold water and used as a "cold water bottle" might be useful.

INCOME TAX.

Emoluments of Assistant.

"J. F. W. A." was employed last year as an assistant "at £150 and all found." He has been assessed at the amount of his salary for the current year *plus* the cost to his principal of his board and lodging.

*** As he was not employed for the whole of the year 1928-29 he is chargeable for the year 1929-30 on the amount of his salary for that year, but he is not assessable in respect of the value of his board and lodging, because that was not received in money or in a form capable of being converted into money—judicial ruling in Tennant *v.* Smith. Probably there is some misunderstanding with regard to the facts, which can be dissipated by an explanation to the local inspector of taxes.

Appointment: Car Expenses.

"C [illegible] workhouse medical officer, and has to v "cottage homes." The two buildings a He had a motor cycle, which he has sold for £18, and has bought a car for £150. What expenses can he claim?

*** We assume that both sections of the work arise from a single appointment, and that "C. F. G." does not receive any unassessed allowance for the expense of travelling between the two premises. He can deduct the original cost to him of the motor cycle, or rather, that proportion of it which is represented by the ratio of the use between the premises to other uses.

Purchase of House for Assistant.

"F. R. F." has had to buy a house for a married assistant. He has paid £110 down, the balance being covered by a mortgage from the local council. Will it make any difference to him whether he bears the expense (rates, interest, etc.) and deducts the amount from the sum otherwise payable to his assistant, or continues the old rate of payment and receives an equivalent rent from the assistant?

*** If our correspondent retains control of the house—that is, does not give his assistant a legal right of tenancy—he can deduct as professional expenses the cash paid to the assistant *plus* the rates paid on the house and the amount of the assessment to income tax under Schedule A. This should come to substantially the same thing as paying the assistant a gross amount and receiving back from him an equivalent rent. But the former will be better for the assistant, inasmuch as he will not be liable to account for the benefit received in the form of free lodgings, but only on the cash paid to him. In either case our correspondent should bear in mind that he cannot claim in respect of the (capital) payment of £110, but should claim that a deduction in respect of the *interest* paid to the local authority should be made each year from the Schedule A assessment on the house in question.

LETTERS, NOTES, ETC.

COULD PREHISTORIC MAN SEE IN THE DARK?

DR. ARTHUR T. TODD-WHITE (Leytonstone) writes: I am of opinion that our prehistoric ancestors could see in the dark; even to-day people vary considerably as to their amount of vision at night. The wonderful paintings found in caves in Spain and France must have been painted without artificial light. I contend that even if prehistoric man had artificial light, he could hardly have invented a smokeless light, and it would have been impossible for him to complete the pictures—for example, the polychromes of Altamira and Font de Gaume—by artificial light, as the smoke would have obliterated them before they were finished. In none of the works on these interesting drawings have I seen any reference to their having been destroyed by smoke. I have no experience of the eyesight of modern savages, but possibly some members of the Association who have come in contact with primitive races could give us some information on the subject. I believe there are races in Africa who live in semi-darkness in the tropical forests; it would be interesting to know whether they can see objects in that semi-darkness better than those of us who have the ordinary allowance of bright daylight.

POTASSIUM IODIDE AS A PROPHYLACTIC AGAINST CATARRH.

DR. EDMUND HOBHOUSE (Wimbledon) writes: Now that the season of catarrhs and influenza is upon us, may I suggest that it is worth while trying small doses of potassium iodide as a prophylactic against infective organisms? The effect seems to be simply that of a centripetal nasal douche, mechanical not bactericidal; in a few observations kindly made for me by Dr. Galt the colonies from the nasal swabs of patients taking this salt were, if anything, slightly more numerous than in the controls; it apparently washes the bacteria out of the tissues, and is sometimes useful in giving a positive result in doubtful cases of phthisis with scanty sputum. As a rule, a daily dose of 5 grains, best taken at breakfast, is ample to produce a slight continuous secretion, which is the result to aim at. As compared with the uncertainty and trouble of nasal douching, this remedy is simple and harmless, except in the few cases where iodism is troublesome; patients must be warned of its effects, especially that they may have all the symptoms of a cold. I have no wish to guarantee the efficacy of this treatment, but the results I have seen are sufficient to justify recommendation of its trial. I first noticed immunity in my own case some years ago while taking potassium iodide to relieve high blood pressure.

VACCINE TREATMENT OF PSORIASIS.

DR. R. W. P. HALL (Windermere) writes: About eighteen months ago I was called in to see a woman, aged 68, who had been troubled with psoriasis for about five years. The condition was widespread, and the skin very irritable. After about a year spent in exploring all the usual methods of treatment, I put her on a mixed stock vaccine composed of various strains of streptococci and staphylococci. There was a definite decrease in the amount of irritation after the second injection, and improvement has been steady and continuous. She has now finished her third course, having had a few weeks between each one, and the skin is normal, apart from a certain amount of staining. One cannot, of course, rule out coincidence, and I should be interested to know whether anyone else has tried this vaccine in psoriasis, and with what results. The vaccine used was the antisepsis vaccine marketed by Messrs. Parke, Davis and Co.

PERSISTENT NASAL DISCHARGE.

DR. F. G. GARDNER (Oxford) writes: In view of the various articles and notes in the *Journal* on persistent nasal discharge, I record a very singular case. A young boy had suffered from a running nose for a long time abroad. He had markedly large tonsils and also adenoids, so I advised the mother to consult a specialist, with a view to operation. When the operation was performed the surgeon, in clearing the nose, removed, in addition to the usual debris, a long pledget of cotton-wool covered with mucus, with which the young patient had obviously plugged his nose; though no plug was visible on ordinary examination. Cotton-wool was much used in the toilet of the nursery, and opportunity made the crime. Naturally the discharge soon cleared up.

THE letters immediately following Mr. T. Young Simpson's name in our issue of October 26th (p. 789) should have been C.B.E.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 45, 46, 47, 51, 52, 53, and 54 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 48, 49, and 50.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 219.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

401. Undulant Fever in the United States.

C. W. WAINWRIGHT (*Bull. Johns Hopkins Hosp.*, September, 1929, p. 133), who records six illustrative cases, states that the American incidence of *Micrococcus melitensis* infection is confined to goat-raising areas, while *Br. abortus* infection is general and widespread. Both infections occur at all age periods, but the occurrence of positive agglutinations in infants suggests the possibility that the disease is more common at this age than is supposed. The majority of infections of both types occur in males. Occupation plays a very important part in *melitensis* infections, the incidence of contact infection from handling goats being so high that the disease has assumed the proportions of an occupational disease. There is also a high incidence of the *abortus* variety among laboratory workers. The symptoms of onset were most severe among the *melitensis* cases, fever being the most constant symptom. Physical examination was strikingly negative in both series. Constipation was an outstanding feature in the *melitensis* group, and was frequently associated with tympanites. Pain, swelling of the joints, and orchitis were much more prominent in the *melitensis* cases. The possibility of latent foci was shown by the presence of the *abortus* variety in an ovarian cyst six years after the onset. Normal or reduced white cell counts predominated in both groups. The author adds that the infection may exist in the absence of the agglutination reaction in the serum, and the organism may be recovered from the blood and urine without demonstrable agglutinins in the serum. Comparison of the two infections shows that *melitensis* infections are usually more severe than those of the *abortus* variety.

402. F. J. HIRSCHBOECK (*Minnesota Med.*, October, 1929, p. 590) summarizes the incidence of undulant fever in the United States, where the disease appears to have become more prevalent in recent years. About 30 cases have been reported in Minnesota since the first case was recorded in 1927. The disease has a tendency to be of the milder *abortus* type in all cases except along the Mexican border, where the more severe caprine type seems to be common. Statistics are not yet available as to the mortality rate for purposes of comparison with the Mediterranean area, where it is 2 per cent. The essential feature in the treatment is rest in bed followed by attention to individual symptoms. Since vaccines and serums have proved unsuccessful, and no specific therapeutic agent has yet been discovered, it is particularly necessary to concentrate on prevention, but the extermination of the disease in cattle appears at present to be impracticable, while the introduction of wholesale pasteurization of milk presents considerable economical difficulties.

403. An Epileptiform Seizure after Lipiodol Injection.

D. OLMER and G. ZUCCOLI (*Paris Méd.*, October 5th, 1929, p. 306) comment on the rarity of nervous complications following the use of lipiodol, and report the case of a man, aged 39, who had previously shown no signs of nerve instability, but who had two *epileptiform attacks after the* intratracheal injection of 20 c.cm. of lipiodol, preceded by 3 to 4 *c.cm. of cocaine solution.* Two or three *minutes* after this injection the patient complained of vertigo, and almost immediately was seized with a *generalized convulsive* trembling of the whole body, with profuse facial sweating, loss of consciousness, biting of the *tongue*, involuntary micturition, and generalized clonic *contractions with deviation* of the head and eyes to the left. The seizure lasted for *two or three minutes, and the patient* lapsed into a semi-coma with stertorous breathing and profuse sweats. A second similar attack occurred after an interval of a quarter of an hour, but some minutes later the patient recovered consciousness, and was found to be quite ignorant of what had happened. A neurological examination *had been negative*, but a second one, three hours after the injection, revealed exaggerated reflexes, a positive Babinski *reaction of the* right side, and a positive Oppenheim one on both sides. The pupils were normal, but headache, nausea, and slight pyrexia were present. The patient recovered fully in two days. The authors remark that two theories have been advanced to explain this attack, one being that it was reflex in nature, the other that it was due to gas embolism. They consider that a *simple* reflex could not account for the convulsive and [illegible] symptoms, and that possibly in making in had been punctured, thus allowing blood stream.

404. The Spleen Index in Malaria.

K. E. SURBEK (*Arch. f. Schiffs- u. Tropen-Hygiene*, September, 1929, p. 461) raises the question whether splenic enlargement is a fair criterion of malarial infection and whether the spleen index is constant for the different clinical types. He has examined 200 Javanese adults, making sure that in all cases parasites of only one kind were present in the blood. The determination of the spleen index was made by palpation with the patient supine, and, it is claimed, with clinical accuracy. Surbek reports that in the case of quartan malaria all the nine patients had splenic enlargement, a condition found also in 64 per cent. of more than 100 patients with the tertian infection; in the case of subtertian infection, however, it was present in only 30 per cent. of over 70 patients. Though the total numbers are too small to be quite conclusive, Surbek publishes them now because the cases with enlarged spleen are apt to be selected from any group for plasmodium index determination; he considers this inexpedient because, although enlargement of the spleen has a certain correlation with the more common tertian infection, there is no such relation in subtertian (tropical) malaria. On the contrary, among his 70 per cent. of subtertian cases which had no splenic enlargement were many patients with severe infection (three died), and cases with heavy ring and crescent infections. He concludes that, where malignant tertian disease is prevalent, the plasmodium index must be determined independently of the spleen index, or many cases of heavy malignant infections will be missed.

405. Massage after Prolonged Exercise.

THE value of massage after long-distance runs has been investigated by Dr. J. MELKA (*Bratislavské Lekárske Listy*, September, 1929, p. 933), who examined the influence of *massage on the hydrogen-ion concentration of the blood*, the respiratory exchanges, the blood pressure, and the pulse. The tests were made on the same athlete under the same [illegible] massage following the exercise. [illegible] as follows. Under the influence [illegible] od, which usually declines after exercise, returns to the normal much more quickly, and the *elimination of carbon dioxide is more rapid.* The consumption of oxygen is higher, and the concentration of carbon dioxide in the alveolar air diminishes more speedily; the total quantity of air expired during the first few minutes following the exercise is considerably increased. The blood pressure and pulse return to the normal much sooner.

Surgery.

406. Acute Pancreatitis.

W. LINDER and L. J. MORSE (*Annals of Surgery*, September, 1929, p. 357) give an analysis of 88 cases of acute pancreatitis, and emphasize the extreme importance of early diagnosis. *This infection may result from pyaemic involvement*, by contiguity, by lymphogenous extension, retrogression of bile *into the pancreatic duct*, or by regurgitation of duodenal contents into the duct of Wirsung. To produce pancreatitis *the bile must be infected*, and an increased biliary pressure must be counterbalanced by unusual sphincter spasm. Acute pancreatitis is not a primary disease, but a sequel, with biliary disease as the usual precursor. In the 88 cases under review fat necrosis was the criterion on which the diagnosis was based. *Females were affected in 88 per cent. of cases*, and 50 per cent. occurred in the fourth and fifth decades. All but eight patients gave a history of previous gastro-intestinal disorder, and 53 per cent. had a definite history of biliary disease. The symptoms, of which epigastric pain is *the most common*, are due to local pancreatic irritation and to the circulation of toxic products, the inflammation of the pancreas resulting in oedema and swelling of the pancreas; the stretching of the pancreatic capsule induces pain; diaphragmatic incursion may be obstructed, and biliary drainage into the duodenum impeded. Circulation of foreign protein and its products of incomplete digestion may explain the severe toxaemia which is sometimes seen, and digestion of blood vessels constitutes the haemorrhagic features. The pain is intensely sev[illegible] persistent, 40 per cent. of the patients [illegible] were in a state of shock on admission. [illegible] of all proportion to the temperature elevation. [illegible] tenderness was present in 66 per cent. of cases, and left costo-vertebral tenderness in 32 per cent. Calculi were found in 44 cases.

and in two instances cholecystectomy had already been performed. The peritoneum usually presented the congested variety of inflammation, fat necrosis being found throughout; the omental and pancreatic peritoneum were most frequently involved. The omentum in acute pancreatitis is greyish-yellow in colour and may feel gritty. The immediate treatment must be to relieve the pressure on the semilunar ganglion and common duct by opening the pancreatic capsule; this is followed by cholecystectomy if the patient's condition warrants it, otherwise drainage of the gall-bladder must suffice to drain the pancreas. The mortality rate was 26 per cent., which should be lowered with earlier treatment of biliary disease; intervention is preferable at a time when the disease is still limited to the gall-bladder.

407. Thyroidectomy in Exophthalmic Goitre.

L. VAN DEN WILDENBERG (*Le Scalpel*, September 28th, 1929, p. 1053) discusses fully the advantages claimed for radiotherapy in exophthalmic goitre, and concludes in agreement with Crile that the benefits so obtained are at the most only temporary. He strongly advocates surgical intervention in this disease, and states that in the majority of cases cure will follow, subject to three conditions: (1) the operative region must not be injured by previous *x*-ray treatment; (2) iodine medication must be used as a pre-operative measure; (3) the operation must be early. Radiotherapy, he believes, injures the operative site and also involves a lamentable loss of valuable time. It may also give rise to very marked adhesions which render a later operation difficult and dangerous. The curative power of iodine, advocated by Labbé, is also doubted, and cures by this drug are considered by the present author to be exceptional. The method advised and employed by van den Wildenberg is bilateral subtotal thyroidectomy performed in two stages. Troubles of compensation, such as hydrothorax, ascites, and oedema of the limbs, are contraindications to operation. In cardiac decompensation thyroidectomy is nevertheless the best measure to adopt, and among 17 patients reported, on whom operation was performed after radiotherapy had failed to produce any benefit, 7 suffered from cardiac deficiency. The author emphasizes the importance of early intervention in minimizing the risk and assuring a cure in most cases. The dangers of late operations, even in grave cases, are much reduced by suitable preparation and skilful technique; even though cure may not result, the benefits are said to be much greater than those obtained by radiotherapy.

408. Duodenal Fistula.

G. RAZZABONI (*Arch. Ital. di Chir.*, July, 1929, p. 253) deals with that special type of fistula which occasionally occurs after extraduodenal operations, chiefly operations on the gall-bladder or right kidney, and records a case. He has made some experiments on dogs to determine the etiology of these fistulae; he found it difficult to produce them by direct injury of the duodenum, but comparatively easy after drainage irritation. Very small fistulae may possibly heal, but the larger ones are more serious, owing to the digestive action of the fluid on the parts, to the haemorrhage, and to the effects they produce on the general health. He discusses minutely the anatomy and physiology of the duodenum, and then describes the symptoms of a duodenal fistula, which, if it occurs, usually sets in during the first week after an operation. Examination of the fluid serves to distinguish its nature. Treatment, except in very minute openings, is surgical, and the author enumerates the commoner methods used; he prefers simple jejunostomy, followed later, if possible, by a more radical treatment of the duodenal lesion. It is important to protect the tissues from the erosive effect of the duodenal discharge by smearing with some oily preparation.

409. Schlatter's Disease and Allied Conditions.

F. BAASTAD (*Norsk Mag. f. Laegevid.*, October, 1929, p. 1106) states that the diseases called after Scheuermann, Kienböck, and Osgood-Schlatter belong to a large group in which the symptoms and morbid anatomy are the same, the only difference being the localization. Several attempts have been made to find a more suitable term for the disease, such as osteochondritis juvenilis and necrosis of the epiphysis and apophysis. The last term is probably the best, as the condition is really a primary necrosis. The importance of trauma in the etiology was shown by C. Mau's experiments. Baastad records two cases of Scheuermann's disease, one in a girl aged 18 and the other in a boy aged 17; both had been engaged in hard work since leaving school. The boy had sought medical advice for the deformity of his back, and the girl had been [illegible] in the back. In both [illegible] the picture of Scheuermann's disease, and good results were obtained by immobilization. Baastad also reports a case of Kienböck's disease in a man aged 26, who had been employed on the railway for three months in pushing stones under the sleepers. During this work he held the spade with the right wrist extended. Owing to increasing pain in the wrist he had had to give up his work, and the skiagram showed characteristic changes in the semilunar bone. The wrist was immobilized for six months, after which the patient had no more pain. The end-result was somewhat reduced mobility of the wrist, especially volar flexion to 153 degrees. Baastad adds that the case is of special interest to insurance companies.

410. Post-operative Gastric Atony.

O. ORTH (*Zentralbl. f. Chir.*, September 21st, 1929, p. 2375), who records a fatal case in a man aged 23, states that the gastric atony which is liable to occur after operations for gastric ulcer or carcinoma usually disappears after a few days' treatment by lavage. There are, however, obstinate cases which for a long time defy every kind of treatment. It is rare for a fatal issue to ensue, Orth having lost only two cases from atony out of the large number of gastric operations which he has performed in the last ten years. In such cases the question arises as to the possibility of congenital abnormalities in the gastric wall. The existence of atrophy of the gastric musculature in Orth's case was in favour of such a view.

Therapeutics.

411. Scillarene in Cardiac Insufficiency.

D. V. BRANISTEANU (*Presse Méd.*, September 7th, 1929, p. 1170) gives an account of the pharmacological action and therapeutic use of the glucoside scillarene. This drug causes arrest of the isolated frog's heart in systole within two and a half minutes, but its action is reversible, since by washing renewed contractions can be induced. By perfusing successive isolated hearts the author found that there was progressively less and less toxic effect, the fourth heart in the series being unaffected; he concluded that the drug enters into a loose union with the heart muscle. The action of scillarene contrasts with that of digitalis in respect of its reversibility; on the other hand, the drug does not resemble strophanthin in its effects, since the latter has a reversible action but no accumulative effects. The author has administered scillarene by intravenous injections of 1 c.cm. daily, and by the mouth in doses of 40 to 60 minims or three to six tablets daily. The patients selected for this treatment were principally cases of chronic cardiac insufficiency associated with valvular lesions, cardio-renal sclerosis, auricular fibrillation, premature beats, and chronic bronchitis and emphysema. In such cases there followed as much amelioration of symptoms as might have been obtained with digitalis, with the exception that scillarene did not modify the rhythm in patients showing auricular fibrillation and extra-systoles; moreover, it was not found to have any influence on the rhythm in a patient suffering from sinus tachycardia. No elevation of blood pressure occurred after the use of scillarene in therapeutic doses, and anginal symptoms associated with aortitis and cardio-renal disease were relieved by it. In 20 out of 100 patients treated the author observed toxic manifestations, principally bigeminy, nausea, and vomiting; they soon disappeared and did not impair the beneficial action of the drug.

412. Arsenical Therapy in Syphilis.

L. HUDELO (*Journ. de Méd. et de Chir. Prat.*, August 10th, 1929, p. 533) says that in the earliest stages of syphilitic infection intravenous arsenical therapy is the best mode of attack; the future of a syphilitic patient depends entirely on the treatment followed during the first two or three months. The author prefers the intravenous method to the intramuscular, since the results are quick and more certain. He enumerates the contraindications to arsenical treatment, discusses cases of arsenic resistance, and comments on the behaviour of arsenic in the various visceral lesions of syphilis. Even in cases where serological tests show a clean record for two years the author advises a six weeks' course of arsenical treatment before allowing marriage. He then discusses arsenical treatment of the pregnant woman and in congenital syphilis. As regards bismuth, he prefers to use the insoluble preparations; the chief indication for bismuth is as a routine treatment, or in cases where arsenic cannot be tolerated. Mercury is not used so much as it used to be, but it may still be useful in conjunction with arsenic; the author prefers intravenous injections of the cyanide in the early stages, and grey oil for less acute cases. In each method of treatment the author gives details of his practice and suggestions as to the best type to use in the various forms of syphilis. He concludes with a short discussion of the place of potassium iodide in the treatment of this disease.

413. Treatment of Frost-bite.

H. NATVIG (*Tidsskr. f. d. Norske Laegefor.*, July 1st, 1929, p. 633) criticizes as irrational the conventional treatment of frost-bite by means of vigorous rubbing with snow or bathing the parts in ice water. When in the cells and fluid of the tissues there have formed more or less large and sharp crystals of ice, rough massage is likely to cause serious injury; when the snow with which the massage is carried out melts, the water injures the skin. This is further illustrated by the fact that if a person is so foolish as to put his face down to drink ice-cold water when the skin has already been devitalized by exposure to cold, the result is a herpes-like eruption about the mouth. After many years' experience in the mountains Natvig has come to the conclusion that much pain and mutilation would be avoided if neither snow nor water was applied to the face and ears when frozen. Instead, the frozen parts should be very carefully pinched with dry fingers or through a glove, cautious massage being given till complete sensation is restored. With these precautions there should be little or no swelling, no vesicles, and the after-effects may be reduced to slight tenderness and desquamation. In the treatment of frozen limbs the patient should be encouraged to carry out active movements. To support these recommendations the author gives detailed reports of cases, including an account of a misadventure which befell himself, and which might have had very serious consequences had he not treated himself on the lines he advises.

414. Diluted Vaccine Lymph.

H. A. GINS (*Zeit. f. Hygiene*, October 12th, 1929, p. 581) considers that the rational way to avoid the severe reactions that have been caused during the last few years by the inoculation of vaccine lymph is to dilute the lymph. Experiments conducted along these lines showed that 50 per cent. glycerinated saline was unsuitable as a diluent, since it led to a rapid weakening in the virulence of the vaccine. On the other hand, very satisfactory results were obtained with 0.25 per cent. phenolized saline solution containing 0.2 to 0.3 per cent. agar; the agar was added to prevent the occurrence of sedimentation. Vaccine diluted 1 in 100 with this diluent proved capable, in a series of primary inoculations on children, of giving 94 per cent. of positive reactions. This dilution, however, was found to be insufficient, and it is proposed in future to dilute the raw material to about 1 in 5,000. The exact dilution to be employed is determined by the titration of the lymph on animals.

Laryngology and Otology.

415. Herpes of the Larynx.

H. R. LANDON (*Arch. of Oto-Laryngol.*, July, 1929, p. 16) defines herpes laryngis as an acute condition characterized by pain in the throat which is intense on swallowing, a variable degree of hoarseness, and the appearance in the larynx of a number of vesicles. The posterior wall of the larynx is the site of predilection. Nothing definite is known about the etiology, but it is generally believed that instability of the nervous system is the basis of the condition and that the common cold is an important factor in the initiation of the disease. Pathologically the lesion consists of a vesicular eruption which affects the aryepiglottic folds, the epiglottis, and the arytenoid area. The true and false cords usually escape, but the lateral walls of the pharynx and the base of the tongue are often affected; in fact, it is rare for the larynx only to be involved. The vesicles are rounded and bordered by a reddish zone; they are from 1 to 2 mm. in diameter and are at first filled with clear serum, but later the contents become turbid. The vesicles burst and form superficial ulcers. The process heals in about fourteen days without scarring. Clinically the disease is ushered in by a mild chill and moderate fever. Discomfort in the throat is followed in about forty-eight hours by very severe pain on swallowing, which may be so intense that even liquids are refused. Hoarseness is usually slight, but may be marked. Within two or three days the symptoms diminish rapidly, and recovery is complete in about fourteen days. On examination the typical picture described under the pathology is seen. Similar conditions of the larynx are found in the eruptive fevers, and the differential diagnosis is obvious from the associated skin lesions. The prognosis is uniformly good, and the treatment is symptomatic, with rest in bed. If dysphagia is very marked the author recommends spraying the throat with 5 per cent. cocaine solution before food, which is, of course, fluid. The author describes a typical case in a man aged 26, and emphasizes the rarity of the disease, only twenty-six cases having been collected from the literature.

416. Mucosus Otitis.

W. KINDLER (*Deut. med. Woch.*, September 6th, 1929, p. 1511), who records an illustrative case in a woman aged 65, states that the clinical picture of otitis media due to *Streptococcus* or *Pneumococcus mucosus* is as follows. Initial fever and pain in the ear with occasional discharge are followed by disappearance of all symptoms pointing to the ear. During a latent interval of several weeks or months, in the course of which extensive destruction is taking place in the mastoid process, the only signs of disease are frequently a remarkable pallor of the skin, unilateral headache, and malaise, with usually a high temperature above 98.6°, and increasing deafness often associated with tinnitus. On examination the drum generally shows only a slight swelling, the so-called "pale infiltration," which often leads to the erroneous diagnosis of a harmless catarrh of the Eustachian tube. It is particularly persons whose general resistance is diminished, especially old people, who are liable to be attacked by *mucosus* otitis. The *Streptococcus* or *Pneumococcus mucosus* is found in from 15 to 20 per cent. of all cases of otitis media, and in about 80 per cent. of these cases an operation on the mastoid process is required.

417. Deafness of Endocrine Etiology.

D. W. DRURY (*New England Journ. Med.*, August 1st, 1929, p. 206) discusses chronic deafness in the light of an endocrine study of 1,000 case histories. Catarrhal inflammation and oto-sclerosis are regarded as its two main causes, the former being an inflammatory middle-ear condition, whereas the latter is neither inflammatory nor tympanic, but a degenerative process mainly affecting the bony labyrinthine capsule. Since very slight structural changes may so profoundly affect function that the resulting functional disorder completely overshadows the defect to which it is due, the author records the result of his study of this large series of cases with respect to the thyroid, pituitary, ovaries, and a non-endocrine group, and the influence of the endocrine secretions on metabolism, regarding otosclerosis as hyperplasia. In 15 per cent. of the cases there was manifest either hyper- or hypo-functional thyroid disease; in 29 per cent. there was pituitary involvement; in 12 per cent. ovarian trouble, either functional or surgical in origin; while 42 per cent. presented a non-endocrine pathology, and the remaining 2 per cent. were not classified. Of the thyroid group, deafness was a presenting symptom in 18 per cent., and of these patients more than 80 per cent. were in the hypo-functional group, tinnitus and vertigo existing in 34 and 15 per cent. respectively. In the pituitary cases deafness was a prominent symptom in 22 per cent., and 75 per cent. of these cases with deafness were of the dysfunctional type of disorder; tinnitus and vertigo were in the ratio of 36 and 24 per cent. respectively. Of the ovarian cases, deafness was a main symptom in 13 per cent.; 34 per cent. of the patients showed tinnitus and 22 per cent. vertigo. In the non-endocrine group deafness occurred as a marked symptom in 19 per cent., with tinnitus in 31 per cent. and vertigo in 20 per cent. Clinical notes of cases illustrating each group are given by the author.

Obstetrics and Gynaecology.

418. Ovarian Tumours containing Thyroid Tissue.

ALTHOUGH about fifty cases of struma ovarii are reported in the literature, there is no standard to determine whether a tumour containing thyroid tissue should or should not be designated struma ovarii, and varying opinions are held by different authorities. Bauer concluded from his case, reported in 1924, that all the so-called thyroid tissue tumours of the ovary are but atypical pseudo-mucinous cystadenomata and not teratomata at all. G. L. MOENCH (*Surg., Gynecol. and Obstet.*, August, 1929, p. 150) does not agree with Bauer's hypothesis, and reports three cases which point to the opposite conclusion. In two of these microscopical examination revealed the typical structure of a cystic goitre, and parvicellular or even hyaline connective tissue separated the various colloid-filled cysts. In neither case was pseudo-mucin found chemically. Both cases were teratomata, and the second contained what was apparently parathyroid tissue. The third case, described by Kovács, seemed to present real evidence that functioning thyroid tissue was present in the ovary. The patient had a struma ovarii both morphologically and chemically, and, in addition, signs of exophthalmic goitre. The symptoms all disappeared after removal of the tumour. Since the tumour was too small to have caused irregular heart action from pressure and since ovarian cyst in itself does not disturb heart action, and since rest in bed could not have returned the heart's action to normal, as it has remained ever since, it is probable that this

beneficial change was due to the removal of actually toxic thyroid tissue contained in the ovarian tumour. From these three cases Mosnch maintains that cases of struma ovarii do occur and that they are teratomata, though the presence of actually functioning thyroid tissue is extremely rare.

419. Pituitary Gland Therapy in Gynaecology.

H. ROULLAND (*La Gynécol.*, July, 1929, p. 395) reports on the use of the extract of the anterior lobe of the pituitary gland in gynaecology. He has been particularly interested in the hormone which influences growth, and the two others which have an action on the genital organs. He asserts that the first hormone (*de croissance*) has been proved to have an undeniable action on development at puberty, acting on both male and female children. Of the latter hormones (*génitales*), one appears to favour luteinization to such a point that it would stop follicular production; the other acts on the follicle itself. As suggested by Evans and Simpson, the growth hormone is inhibited by the genital hormone when this begins to be effective at puberty. On the anterior lobe, through the medium of the ovary, depends the functioning of the entire genital tract. The author considers that these statements have been confirmed clinically. Extract of the anterior lobe he found particularly indicated in amenorrhoea associated with the infantile type—young girls with ill-developed figure, very small genital organs, secondary characters hardly present, and small thyroid glands. The thin asthenic type of patient with long limbs and late-appearing or irregular menstruation associated with emotional symptoms also responded well. The author's method of treatment was to give 15 drops of a 1 in 1,000 solution of adrenaline three times a day for ten days before the period. For ten days following the period one cachet was given three times a day containing 1 gram of calcium lactate, 0.1 gram of extract hypophysis anterior lobe, and 0.3 gram of calcium phosphate. This treatment was continued for two months, and was then suspended for several weeks. The author gives details of three cases which successfully responded to this treatment.

420. The Treatment of Puerperal Infection.

ACCORDING to VAN CAUWENBERGHE (*Bruxelles-Méd.*, August 18th, 1929, p. 1164) there is no certain and definite treatment of puerperal infection. Prophylaxis is the most effective weapon, and, as an active therapy, auto-haematolysis seems the most promising, especially in streptococcal infection, the commonest form. Since some of the gravest attacks of puerperal infection occasionally terminate spontaneously, it is difficult to estimate the value of such surgical remedies as hysterectomy, which, if employed at all, must be performed quite early to be of any use. The author comments on the advantage of ensuring thorough pre-natal treatment and of limiting digital examination during labour; a very careful vulvar toilet is necessary, but the author deprecates douching except where purulent discharge is present, when he uses a solution of argyrol and glycerin. Antistreptococcal serum given prophylactically does not seem to do much good, but the local application of a vaccine has had good results. In the treatment of declared infection (local, general, or haematogenic) curetting is generally condemned at this stage; it is essential to isolate the organism concerned and prepare an autovaccine. The author briefly enumerates the different types and kinds of injection, and then describes autohaemolysotherapy, which he considers the most hopeful. He mixes 8 c.cm. of blood with a solution containing 10 cg. of sodium cacodylate and 5 mg. of calcium chloride dissolved in 20 c.cm. of distilled water. About one-third of this mixture is injected into the buttock, and a second third is injected four or five hours later. The author supplies six charts showing the effect of this treatment in rapidly bringing down the temperature, improving the general condition, and producing definite cure. No shock followed this treatment, and it is said to be particularly effective when there is a pure streptococcal infection. With the exception of cases of late infection and severe metrorrhagia the author doubts the value of hysterectomy in puerperal infection.

421. Toxaemias of Pregnancy.

H. J. STANDER (*New England Journ. Med.*, September 5th, 1929, p. 458) records an analysis of 801 cases of toxaemia of pregnancy which occurred in the Johns Hopkins Hospital between May 1st, 1923, and May 1st, 1929. The total incidence of all types of toxaemia was 9.37 per cent. The author suggests the classification of toxaemias of pregnancy as (1) vomiting of pregnancy; (2) existence of "low reserve kidney"; (3) nephritis complicating pregnancy; (4) pre-eclampsia; and (5) eclampsia. The statistics are analysed as to the incidence, urine and blood chemistry, pre-natal care, maternal and foetal mortality rates, and treatment. Stander concludes that the vomiting of pregnancy nearly always responds to conservative treatment, which includes isolation and an initial period of starvation. The low reserve kidney is not an alarming complication, and is best treated by rest in bed and dietary measures. Nephritis must always be regarded as a very serious complication of pregnancy, termination of pregnancy, and even sterilization, often being necessary. Conservative treatment is effective in most pre-eclamptic conditions, but radical intervention may become necessary. Eclampsia, in the author's opinion, is best treated by conservative measures, with radical intervention in the exceptional cases in which the patient does not respond to medical therapy. The severity of the eclampsia may be gauged by the uric acid content of the blood and the CO_2 combining power of the serum. Acidosis must be treated as it arises. The author emphasizes the importance of pre-natal care both in preventing some of the toxaemias and in detecting patients who need immediate treatment.

Pathology.

422. Chemistry of Pulmonary Oedema Fluid.

G. BLIX (*Upsala Läkareför. Forhand.*, September 1st, 1929, p. 787) finds that very little information can be gained from the literature regarding the chemical composition of the fluid in pulmonary oedema, most of the data being antiquated and only of a qualitative kind. It is generally agreed that the fluid contains abundant quantities of protein. The only quantitative estimates hitherto made are those of Starkow, who found a protein content of 2.94 to 3.33 per cent. Blix has recently conducted three examinations of the pulmonary oedema fluid from a man, aged 62, suffering from angina pectoris. The composition of the fluid was much the same on the three occasions. As in most transudates, the protein content in the oedema fluid (2.35 or 2.85 per cent.) was much lower than that of the blood serum (7.26). In oedema with the low protein content the specific gravity was relatively low—namely, 1010–1012, as compared with that of the blood (1026). As is the rule in transudates, the albumins (2.05–2.51) predominated over the globulins (0.26–0.32). The values of the lipoids (0.01) were much below those of normal serum, whereas the chlorine values (0.32–0.36), although relatively low, lay within the normal range.

423. The Sedimentation Test in Diabetes Mellitus.

WISSELINCK (*Münch. med. Woch.*, August 16th, 1929, p. 1373) has performed a series of investigations on patients with diabetes mellitus to ascertain what effect the amount of sugar in the blood and urine, ketonuria, and insulin had on the sedimentation rate of red blood corpuscles, since other workers had obtained conflicting results. Westergren's technique and normal standards were adopted and over 300 tests were made on 63 diabetics. In 26 of these the sedimentation rate was normal; in some of the remainder it was increased, and in others diminished. Wisselinck came to the conclusion that on the whole the rate was independent of the clinical condition in diabetes, that the amount of sugar in the blood and urine and the administration of insulin had no constant effect on the rate, and that it was of no prognostic value in diabetes mellitus.

424. Brucella abortus in Milk.

ACCORDING to M. J. KING and D. W. CALDWELL (*Amer. Journ. Med. Sci.*, July, 1929, p. 115), patients with lowered resistance (due, for instance, to tuberculosis, chronic tonsillitis, or ulcerative conditions of the intestinal tract) who drink raw milk infected with *Br. abortus* may develop agglutinins in their blood serum with or without appreciable clinical symptoms of undulant fever. Of 851 patients and 156 staff in the sanatorium who used raw milk, 91 (9 per cent.) showed *Br. abortus* agglutinins when their serums were diluted 1 in 15 or higher; 24 of the 91 patients had agglutinin titres varying from 1 in 24 to 1 in 3,200. The persistent presence of *Br. abortus* agglutinins in human serum for months or years after the patients recover was evidence of infection with *Br. abortus*. The presence of this organism in the blood serums of cows did not necessarily imply that they were discharging it in their milk. In a herd of 151 animals no evidence was obtained of the infection of the milk of cows though their serums agglutinated at 1 in 60, while cultures of *Br. abortus* were obtained from the milk of only 23 cows out of 56 with titres of 1 in 120 or higher. *Br. abortus* was not isolated from the blood or from the urine

SALTAIR SURGICAL SERVICE

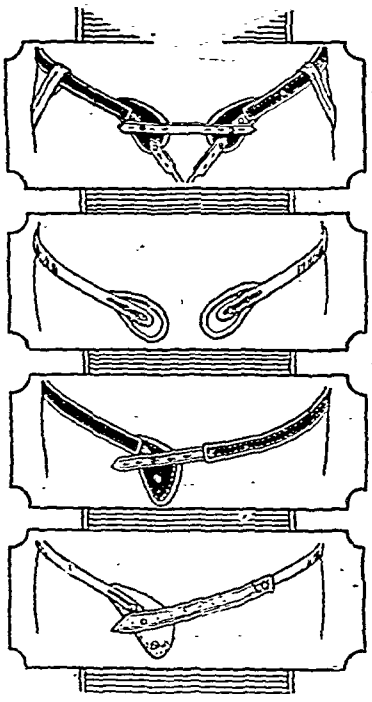
SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

The Medical Profession with the aid of Salt's Surgical Service CAN (except in cases of gross carelessness on the Patient's part) PREVENT future cases of SEVERE HERNIA and greatly alleviate those already existing.



WHY ARE THERE SEVERE CASES OF HERNIA?

Every medical man will agree that severe Hernia is attributable to one or two causes:—

1. Neglect

whereby medical advice or surgical aid is not sought.

2. Fitting of Inefficient Appliances

The first case is beyond our control or that of the medical man until he is consulted. In the second case the patient either tries one of the much-advertised "Rupture Cures" or purchases a "Stock Truss," both of which are universal appliances—non-adjustable, and made to fit short, stout, tall, or thin—and, owing to inadequate support, the Hernia develops.

Out of more than 25,000 cases of developed Hernia personally fitted by us during the last 20 years, in the great majority of severe cases the history proved that the patients had obtained a "Stock Truss" or "Universal Appliance" in the first instance.

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

"ARDENTE" STETHOSCOPE. *Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.*

MEDICAL REPORTS. *Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request*

Advise your patients

As a preventative of winter chills and ills, the body *must* be protected by wearing underclothes which keep warmth *in* and cold and dampness *out*. Wool, as you know, does this better than any other material.

Advise your patients to wear Wolsey pure wool underwear next the skin and they will be safeguarded against the vagaries of our ever-changing climate. It keeps the body at an even temperature. There is no next-the-skin wear to compare with

WOLSEY

PURE WOOL UNDERWEAR

Wolsey Ltd., want to give you solid facts, and therefore invite you to send for a free copy of the booklet, "Why Wool should be worn," compiled by The British Research Association. It should be read by every man and woman who has the health of the British Public at heart.

Evening Wear *for* Doctors

£1 PER MONTH

It is because the West End Tailor is a past master in the art of providing the right clothes for individual personalities that his assistance is invariably sought for by Doctors in matters relating to evening wear.

At Keith Bradbury's, men obtain the right materials, fashioned to enhance their personalities, plus a FREE VALET SERVICE for the care of their clothes after purchase.

Every consideration is given to the financial convenience of customers and arrangements are made for accounts to be disposed of either half-yearly, quarterly, or upon a £1 per month basis.

The prices below are unusually reasonable for West End Tailoring and should tempt you to give Keith Bradbury a trial, expressly on the understanding that your satisfaction is a foregone conclusion.

Catalogue and patterns gladly sent on request.

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

EXTRACT FROM THE "BRITISH MEDICAL JOURNAL," DEC. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health . . . and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition. . . . MADAME ROSE has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

COLLENDER'S SPLINTS

(Patented in the Leading Countries of the World)

An evolution of the Thomas Splint—all the advantages of the Thomas Splint are preserved, with many important improvements, additions, and modifications.
They are supplied in strong fitted case, and enable 10 fractures simultaneously to be put up in any position obtainable by Thomas arm or leg Splints.
They provide the most modern methods of accurate extension, and safe transport of the patient is assured. Complete splints suited to limbs of any dimensions can be constructed in a few minutes from the component parts.

All members are interchangeable, standardised, numbered, and replaceable. They are made of Duralumin, which is untarnishable, exceedingly light in weight, and of great tensile strength. They can be immersed in sterilizing fluid without injury and can be used repeatedly.
Collender's Splints will be found invaluable for Hospital Emergency work and particularly to District Surgeons, Mines, Ranches, Lumber Camps, Railways, Shipping Companies, Industrial Plants, and all places remote from surgical help.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the s-ashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 66, Northampton), who can be seen in London by appointment.

BELVOIR NURSING HOME,
ASTON-ON-TRENT, DERBY.

FUNCTIONAL NERVOUS DISORDERS & CHRONIC MEDICAL CASES.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical Treatment, Radiant Heat, X-ray, and Ultra-violet Light is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week; for Chronic Medical Cases from 3 guineas a week. For further particulars apply to—

Dr. E. M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: Shardlow 16.

PROVIDES HIGHLY SUCCESSFUL ORAL AND POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS.

Special Preparations for all Surgical Qualifications.

F.R.C.S.ENGLAND.	CH.M.EDINBURGH.
(Primary & Final.)	M.C.CANTAB.
F.R.C.S.EDINBURGH.	M.S.LONDON.

And all other Surgical Degrees and Diplomas.

¶ The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.
¶ Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Examinations on several previous occasions get through without difficulty after going through our courses.
¶ The Surgical Tutors of the College all hold either the M.S.Lond. or F.R.C.S.England, or both, and are highly experienced teachers.
¶ The Postal Courses are thoroughly clear, concise, and up to date, and the test questions are carefully selected from those set at previous Examinations, so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time, and much unnecessary reading is saved.

VALUABLE BOOK
"How to Pass the F.R.C.S.," free on application to the Secretary.

Birmingham Union.

DUDLEY ROAD HOSPITAL.

SURGEON.

Applications are invited from fully qualified registered Medical Practitioners for the above appointment.

The Hospital accommodation is fixed by the Guardians at 926, divided into Medical, Surgical, Children's, Infectious, Gynæcological and Obstetrical Sections. There are completely equipped Pathological and Biochemical Laboratories, X-ray, Electrical, Massage, Sunlight, and Dental Departments. Approximately 6,000 operations are performed annually.

Candidates for the appointment must have had good Surgical experience, and be Fellows of the Royal College of Surgeons (*England*).

The scale of salary will be £700, rising by annual increments of £50 to a maximum of £1,000 per annum, and the salary of the successful candidate will be fixed within the scale according to experience and qualifications.

Furnished quarters, *rations*, laundry, and attendance will be provided by the Guardians. Alternatively, a cash allowance will be paid if the officer appointed is non-resident. A deduction of 2 per cent. will be made from the salary and value of emoluments under the provision of the Poor Law Officers Superannuation Act, 1896.

Further particulars of the appointment may be obtained from the Chief Medical Officer, F. W. ELLIS, Esq., M.D., F.R.C.S., Dudley Road Hospital.

Applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, must be forwarded so as to reach me not later than 11 a.m. on Monday, November 25th.

Union Offices, Birmingham. November 4th, 1929.

C. P. BEECH, Clerk to the Guardians.

Applications, accompanied by recent testimonials and references, should be sent on or before Saturday, November 16th, to the undersigned from whom further details may be obtained.

W. M. GIBBONS, Registrar.

The University of Sheffield.

FACULTY OF MEDICINE.

The Council of the University are about to make an appointment to the post of LECTURER IN PATHOLOGY in the University. The salary offered is £500 per annum. Applications, accompanied by recent testimonials and references, should be sent on or before Saturday, November 16th, to the undersigned, from whom further details may be obtained.

W. M. GIBBONS, Registrar.

Parish of Stepney.

MEDICAL SUPERINTENDENT.

The Guardians invite applications from fully qualified registered Medical Practitioners for the post of Medical Superintendent at their ST. PETER'S (WHITECHAPEL) HOSPITAL, situate at 74, Valiance Road, Whitechapel, London, E.1.

The inclusive salary will be at the rate of £900 per annum, together with the emoluments of residence, *board*, coal, gas, *wates*, and attendance, valued for the purposes of superannuation at £210 per annum.

The candidates must have previously held a *resident Hospital* appointment and have had administrative *experience* in a Poor Law Hospital or similar *Institution*.

The salary and emoluments will be subject to the customary deductions for superannuation, and the person appointed will be required to pass a medical examination as to fitness before commencing duties.

The appointment is *subject* to any provisions affecting officers in the Local Government Act, 1929.

In addition to the duties of Medical Superintendent of the Hospital, the appointment includes the duties of Chief Medical Officer for the outdoor medical work in Area "A" of the Parish and also the medical examination of certain sections of the Board's staff.

The Hospital is one of three Hospitals administered by the Guardians; is certified for 829 beds; and is also a Centre for Ophthalmic and Mental Observation Cases in Stepney. All classes of cases (*medical, surgical*, and maternity) are dealt with, and there is a *staff of Visiting Consultant Specialists*. The Hospital *has*, in addition, Training *Schools* for Nurses, both male and female.

Further particulars as to the duties and forms of application may be *obtained* from the Medical Superintendent, or will be forwarded from this office upon receipt of a stamped addressed foolscap envelope, and must be returned to me by *not* later than Wednesday, November 20th.

By Order,
S. MCCLELLAND, Clerk to the Guardians.

Administrative Offices, Bancroft Rd., Mile End, London, E.1. November 2nd, 1929.

The Radium Institute,

Riding House Street, London, W.1.

Applications are *invited* from duly qualified Medical *Practitioners* for the post of WHOLE-TIME ASSISTANT (non-resident) in the MEDICAL DEPARTMENT of the Institute.

The salary will be at the rate of £600 per annum, and the appointment will take effect as from January 1st, 1930.

The *present* House Surgeon is a candidate for the post.

Applications, stating age, qualifications, and experience, with copies of three recent testimonials, must be received at the Institute not later than November 12th.

Canvassing, either directly or indirectly, is not permitted.

THOS. A. GARNER, Secretary.

St. John's Hospital, Lewisham, S.E.13.

There is a vacancy for a RESIDENT MALE CASUALTY OFFICER. Salary £100 p.a. The appointment is for six months. Applications, with copies of testimonials, should be sent to the Secretary of the Hospital as soon as possible. The successful *applicant* must be prepared to begin duty at once.

County Borough of Derby.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH.

The Council of the County Borough of Derby invite applications for the appointment of Medical Officer of Health for the Borough. Commencing salary £1,100 per annum.

Candidates must be duly qualified Medical Practitioners possessing a recognized Diploma of Public Health and the requisite qualifications required by Acts of Parliament and Regulations of the Ministry of Health. Any applicant appointed must devote the whole of his time to his duties and not engage in private practice.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and the selected candidate will be required to pass a medical examination satisfactory to the Corporation.

Age not to exceed 40 years in the case of any applicant not already in the service of the Corporation.

Other conditions being equal, preference will be given to applicants possessing the necessary qualifications who have actually served in the Forces overseas.

Particulars of qualifications and duties of the office and terms and conditions of service, together with forms of application, may be obtained from the undersigned, and applications endorsed "Medical Officer of Health" (on the form supplied only), accompanied by copies of not more than three recent testimonials, to be sent to the Town Clerk, Derby, not later than Saturday, November 16th.

Canvassing, either directly or indirectly, will be a disqualification.

Market Place, Derby. G. TREVELYAN LEE, Town Clerk.

October 30th, 1929.

City of Manchester.

APPOINTMENT OF ASSISTANT TUBERCULOSIS OFFICER.

The Public Health Committee invites applications for the position of Assistant Tuberculosis Officer at a commencing salary of £650 per annum, rising by annual increments of £25 to £750 per annum. (First increment January 1st, 1931.)

Candidates must be fully qualified Medical Practitioners having special knowledge of Medical and Surgical Tuberculosis. Candidates should state whether they possess the Diploma of Public Health.

Applications, stating age, qualifications, and experience, with copies of not more than three recent testimonials, and endorsed on the envelope "Assistant Tuberculosis Officer," must be addressed to the Town Clerk only, and not to members of the Committee or Council, and must be received by him not later than Monday, November 18th.

The gentleman appointed will be under the administrative control of the Medical Officer of Health and the immediate control of the Senior Tuberculosis Officer. He will be required to devote the whole of his time to the duties of his position, to execute the Deed of Service, and to contribute to the Corporation Superannuation Fund.

Canvassing in any form, oral or written, direct or indirect, is prohibited.

By Order,
Town Hall, Manchester. F. E. WARBRECK HOWELL, Town Clerk.

City of Birmingham.

ASSISTANT MEDICAL OFFICER.

The Public Health Committee invite applications for one of the posts of Assistant Medical Officer for Public Health duties. Candidates must be qualified Medical Practitioners and possess a degree or diploma in Public Health or Science. The candidate appointed will be required to join the Birmingham Corporation Superannuation Scheme, and for the purpose to pass a medical examination. The appointment will be terminable by one month's notice on either side. *Salary £750 per annum*

Applications, endorsed "Assistant Medical Officer of Health," and to be accompanied by copies of three recent testimonials, to be made on a form to be obtained from the Medical Officer of Health, The Council House, Birmingham, and returned to him on or before Saturday, November 16th. Canvassing will disqualify.

Royal Chest Hospital,

City Road, E.C.
(Royal Northern Group of Hospitals.)

CLINICAL ASSISTANTS are required in the Out-patient Department on Monday and Thursday afternoons. Ladies are eligible. Applications should be forwarded to the Secretary.

County Council of Durham.

MATERNITY AND CHILD WELFARE.

ASSISTANT WELFARE MEDICAL OFFICER.

The County Health Committee invite applications for the appointment of an Assistant Welfare Medical Officer (woman), at a commencing salary of £600, rising by annual increments of £25 to £650 per annum. Travelling expenses will be paid by the County Council according to scale.

Applicants must be registered Medical Practitioners of not less than three years' standing, and not exceeding 45 years of age, with special experience in Maternity and Child Welfare work and its organization. The person appointed will be required to reside in Durham City or other approved centre and to devote her whole time to the duties of the office, and must be prepared if called upon to act as Locum Tenens to other members of the Medical Staff of the County Medical Officer, and will be debarred from engaging in private practice. The D.P.H. or its equivalent will be considered an additional qualification.

The appointment will be terminable by three months' notice on either side.

A condition of the appointment is that on marriage the officer will be required to vacate her post.

The appointment will be subject to the provisions of the Local Government and Other Officers *Superannuation Act, 1922, and to a* medical examination, as required by the Council for the purposes of the Act, and the statutory contributions to the Superannuation Fund under that Act will be deducted from the salary.

Applications, marked "Assistant Welfare Medical Officer," together with copies of not more than three recent testimonials, must be sent to the County Medical Officer, Shire Hall, Durham, not later than November 18th.

Shire Hall, Durham. HAROLD JEVONS, Clerk of the County Council.

October 28th, 1929.

Royal Cripples Hospital,

BIRMINGHAM.

Applications are invited for the post of HOUSE SURGEON, vacant December 1st. Salary £200 per annum, with board and residence. The appointment, which is for a period of six months, is renewable on the discretion of the Medical Board, and is terminable by one month's notice on either side. Preference will be given to candidates with previous experience in general and orthopædic hospitals.

Applications, with copies of three recent testimonials, to be sent to the undersigned not later than November 18th.

Miss CHRISTINE COX,
Royal Cripples Hospital, 80, Broad St., Birmingham. Gen. Secretary.

Borough Mental Hospital,

ROWDITCH, DERBY.

SECOND ASSISTANT MEDICAL OFFICER wanted. Commencing salary £350 per annum, rising by £25 per annum to £450, with an additional £50 per annum if in possession of the Diploma in Psychological Medicine, with board, apartments, attendance, and laundry. Candidates must be unmarried and registered under the Medical Act. The appointment is subject to 3 per cent. deduction on salary and emoluments under the Asylum Officers Superannuation Act, 1909. Apply, not later than November 19th, stating age and full particulars, together with copies of three recent testimonials, to the Medical Superintendent.

Blackburn and East Lancashire

ROYAL INFIRMARY.

FOURTH HOUSE SURGEON (male), to commence duties December 1st, required at a salary of £130 per annum, with board, residence, laundry, etc.

The Hospital contains 240 beds, with X-ray, Massage, *V.D.*, Eye, Ear, Nose, and Throat Departments, Pathological Laboratory, etc. There is no outside work.

Applications, with copies of testimonials, stating age, nationality, experience, etc., to be sent at once to the undersigned.

Royal Infirmary, Blackburn. NATHAN A. SMITH, Gen. Supt. & Sec.

Darlington General Hospital.

(120 Beds.)

Wanted, HOUSE SURGEONS, Senior and Junior, male, British, fully qualified. Salaries £150 and £125 per annum respectively. Board and residence. Applications, stating age, experience, and qualifications, together with copies of two recent testimonials, to be addressed to me forthwith.

A. RIDDLE, Secretary.

Worcestershire County Council.

ASSISTANT COUNTY MEDICAL OFFICER.

The above-mentioned Council are about to appoint an Assistant County Medical Officer, and applications are now invited for this post.

Applicants must be registered Medical Practitioners between the ages of 25 and 45.

The duties will include attendance at Infant Welfare and Ante-Natal Centres, and the medical examination of elementary and secondary school children. Special Post-Graduate experience in Children's Diseases is especially desirable.

The officer who is appointed will work under the supervision of the County Medical Officer, *and will be* required to reside in the district assigned to him or her by the County Council, and to devote the whole of his or her time to *the work.*

The salary will be £600 per annum, with an allowance of £140 per annum for use of own motor car, or a car will be supplied for County work.

The engagement will be subject to three months' notice on either side.

Applications (on forms to be obtained from the County Medical Officer, 29, Foregate St., Worcester), accompanied by not more than three recent testimonials, must be received by 12 noon on Thursday, November 28th, addressed to the County Medical Officer, 29, Foregate Street, Worcester.

Canvassing disqualifies, and neither the names of the Members of the County Council nor of the Committee will be supplied.

(Signed) C. H. BIRD, Clerk of the County Council.

Shirehall, Worcester.
November 5th, 1929. (V.135.)

Parish of Ipswich.

ASSISTANT RESIDENT MEDICAL OFFICER (Female).

The Guardians of the Poor of the Parish of Ipswich invite applications from fully qualified Medical Women for the appointment of Assistant Resident Medical Officer at HEATHFIELDS INFIRMARY, HEATHFIELD HOUSE, and ST. JOHN'S HOME FOR CHILDREN. Salary £250 per annum, with board and residence. The appointment is subject to termination by six weeks' notice on either side.

The accommodation of the Heathfields Infirmary is for about 250 patients, and of Heathfield House about 230 inmates. The number of children in St. John's Home is about 150.

The candidate appointed will be required to act generally under the direction of the Visiting Medical Officer, and to give lectures to the Probationer Nurses.

Applications, stating age, qualifications, and experience, accompanied by copies of not more than three testimonials, to be sent to me endorsed "Assistant Resident Medical Officer," not later than Monday, November 25th.

L. W. GREENHALGH, Clerk to the Guardians.

Guardians' Offices, 19, Tower St., Ipswich.
November 5th, 1929.

South London Hospital for

WOMEN,

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. PARTNERSHIP.—In a most desirable outlying residential suburb a suitable Partner (married preferred, about 30 years of age, and experienced) can acquire a share (producing at first about £1,250 p.a., with further shares up to one-third at arranged intervals) in an old-established good mixed class Practice, averaging nearly £10,000 p.a. Very good house, with ample accommodation, nice garden, etc. Premium 2 years' purchase, half down and balance by instalments. Good society, sport, and excellent educational facilities. Short preliminary assistantship essential.
2. PARTNERSHIP.—FAVOURITE SOUTH-COAST WATERING-PLACE.—Third Partner required in very old-established mixed-class and increasing Practice, the income of which for last financial year amounted to over £4,000, including panel of 3,300 and appts. producing £2,500. Third share offered to commence with, with prospect up to one-half. Visits 3/6 to 10/6. Very little midwifery. Suitable house obtainable. Premium 2 years' purchase. Short preliminary assistantship offered.
3. PARTNERSHIP.—CHESHIRE.—Within a few miles of a large town).—In a pleasant residential district (pop. over 7,000), the half share of a very old-estab. Practice worth about £4,000 p.a. Patients all classes. Suitable house available on rental. Premium 2 years' purchase, part by instalments. Excellent social and good educational facilities.
4. SOUTH MIDLANDS.—FAVOURITE RESIDENTIAL TOWN.—PARTNERSHIP.—A one-fifth share in a very old-estab. good mixed-class non-dispensing Practice. Income last year over £5,500, and very rapidly increasing. Panel of 1,700. Fees 5/- to 10/6. Mids. 4 to 25 gns. Suitable house available. Excellent schools, sport, and social life. Premium £2,000.
5. PARTNERSHIP.—Within 100 miles of London.—A suitable Partner, experienced in surgery, can acquire either a fourth, third, or half share in a very old-established Practice situated in a desirable country town. Income over £4,200 p.a. (this year to date £4,385), including appts. worth £300 and panel. Visits up to 31/6. Good house available with ample accommodation. Price, freehold, £2,000. Premium for share 2 years' purchase. Up-to-date Cottage Hospital. Excellent society, sport, etc.
6. LARGE HOSPITAL TOWN, within 50 miles of London.—PARTNERSHIP.—A one-fifth share, to commence with, in well-established mixed general Practice. Income about £8,000, including large panel. Fees 3/6 to 21/-. Good house available, with large garden. Price £2,800, large part on mortgage. Premium 2 years' purchase, £2,000 down and balance by instalments. As there is unlimited scope for surgery, purchaser must have an F.R.C.S.
7. SOMERSET.—Near Hospital Town, in very pleasant residential district, an old-established unopposed Country PRACTICE (held by Vendor, who is retiring, over 20 years) averaging over £900 p.a., including panel (producing about £400 p.a., with mileage) and appts. Visits 3/6 to 21/-. Railway station in place. Nice house (5 bedrooms, dressing and bathroom, etc., garden). Price, freehold, £1,500, of which £1,000 on mortgage. Premium £1,400. Good society, excellent educational facilities.
8. DEATH VACANCY.—CORNWALL.—Good town within 2 miles of sea.—Old-estab. middle and working-class PRACTICE. Income about £1,700, including panel of 670. Fees 3/6 to 5/6. Large house, having electric light. Garden. Garage. Can be rented on lease or will be sold. Excellent sport. Premium £2,000 or near offer, part by instalments. Locum in charge.
9. LONDON, EAST.—(Within 1 mile of Liverpool Street).—Old-established PRACTICE in thickly populated district worth last year £848, including panel of 520. Small house (surgery, waiting room, dispensary, lounge sitting room, 2 bedrooms, bathroom, etc.). Rent on lease £60 p.a. Premium £1,400, or near offer, to include fitted carpets, linoleum, and curtains.
10. LONDON, S.W.—Well-established non-panel PRACTICE, producing last year nearly £900. Accommodation suitable for a single man, or could be worked as "lock-up." Premium 1½ years' purchase. Ill health reason for sale.
11. MANCHESTER.—Rapidly growing Suburb within 5 miles of the City.—Old-establi[sh]ed [PR]ACTICE, producing a steady average in[come] ly 1,400. Fees 3/6 to 10/6. Large hou[se] d, £2,500, or would be let on lease a[t]
12. LONDON, [SUB]URB.—PARTNERSHIP. —A one-fo[r] 12 months) in a very old-established non-panel and non-dispensing better-class Practice. Average income £6,000. Fees 7/6 to 10/6. Large double-fronted house [a]rtner retiring. Premium 2 years' purchase.
13. —A one-half-share in a very old-established and appointments. Visits 3/6 to 42/-. Midwifery from panel 30 cases. Very attractive house, 2 reception, 5 bedrooms, etc. Large garden. Can be rented on lease at £80 p.a. Excellent sport and schools. Premium 2 years' purchase.
14. PARTNERSHIP.—Pleasant Seaside Resort within 40 miles of London.—A third Partner required in very old-established mixed-class Practice worth about £5,000 p.a. (this year it is anticipated receipts will be £6,500), including panel about 1,800. Visits 5/- to £1 1s. Only 20 to 30 midwifery cases yearly. Prospect of being appointed on Hospital staff within reasonable time. Suitable flat available or house to be obtained. Premium 2 years' purchase.
15. PARTNERSHIP.—HOME COUNTIES.—WITHIN FIFTY MILES OF LONDON.—A share representing over £1,300 p.a. is offered in a very sound good middle-class Practice situated in an attractive residential district. Panel of over 3,500. Very suitable house, with 3 reception, 4/5 bedrooms. Garden. Garage. Rent on lease £60 p.a. Good sport and schools. Premium 2 years' purchase, part by arrangement.
16. STAFFORDSHIRE.—LARGE TOWN.—PARTNERSHIP.—A one-third share in an old-established mainly industrial Practice. Average income £3,700. Panel of nearly 5,000. Fees from 2/-. Good house available. Purchaser should be keen on obstetrics. Premium 1½ years' purchase.
17. SOUTH WALES.—NEAR LARGE TOWN.—COUNTRY PRACTICE.—Income for the last year £1,450. Panel of 1,300. Practically all contract fees. Good house on lease, rent £60. Premium £1,500, £1,000 down and instalments over 2 years.
18. CORNWALL.—Old-established increasing PRACTICE in pretty district, 5 miles from Hospital Town, and within 10 miles of the sea. Income last year £1,504, including Union and Vaccination (£105) and panel of 780. Visits 5/- to 10/6, medicine extra. Nearest opposition 8 miles. Railway station near. Detached house, professional rooms, 2 reception, 5 bedrooms, bathroom, etc.). Garden. Garage. Rent on lease £45 p.a. Premium £2,100.
19. PARTNERSHIP.—NORTH WALES.—(Pretty district on Borders of Cheshire).—The THIRD or HALF SHARE of old-established PRACTICE worth over £4,000 p.a., and consisting mainly of panel (producing over £2,100) and appts. worth about £1,600. Only 50 mid. cases yearly. Expenses light. Suitable house available if half share taken (net rent £50 p.a.), otherwise inexpensive rooms. Premium for share 1½ years' purchase.
20. EASTERN COUNTY.—(Within easy reach of sea).—PARTNERSHIP, after preliminary Assistantship, at a salary of £400 p.a., out-door. A one-third share is offered in a good-class general Practice averaging approximately £3,300 p.a. Panel of 1,300. Cottage Hospital. Ingoing partner must be a gentleman and fond of country life. Premium 2 years' purchase.
21. SUSSEX.—In a very pretty district amidst delightful surroundings an old-established PRACTICE worth at present about £1,150 p.a., but offering exceptional scope for development. Panel of 525 and Union appt. Fees 3/6 upwards. Opposition 3½ miles distant. Rail[way] [sta]tion in its own grounds of 2½ acres and [gar]. Ample accommodation. Central heati[ng]. Freehold for sale. Prem. £1,700.
22. PAR[TNERSHIP]. Favourite Residential and Holiday Reso[rt]. crease later, in a well-established non-dispensing chiefly better-class Practice. Average income over £3,000 p.a., with large scope. Fees 5/- to 21/-. Very little mid. Good corner house, with 4 reception, 6 bedrooms, etc. Premium 2 years' purchase. Scope for surgery.
23. SOUTH COAST.—FAVOURITE HEALTH RESORT.—Good mixed PRACTICE, averaging over £700 p.a., and offering scope for increase. Panel of 720. Fees 5/- upwards. Very nice house, with 2 reception, 4/5 bedrooms, etc. Garden. Premium 1½ years' purchase.
24. NORTHANTS.—Unopposed Country PRACTICE, within easy reach of large town, old-established and averaging over £1,600 p.a., including about £675 from panel and £80 from appts. Fees from 2/6 to 21/-. Suitable house available. Price £1,000. Premium 1½ years' purchase.
25. WEST OF ENGLAND.—LARGE TOWN.—PARTNERSHIP.—A share representing about £900 p.a., including about £600 from panel, is offered in a well-established middle and working-class Practice. Fees 2/6 upwards. Suitable house, with 2 reception, 4—5 bedrooms, etc. Garden. Garage. Rent on lease £40 p.a. Premium £1,200 cash and balance by arrangement.

Food Poisoning—
The Kaylene Treatment

The following letter has been received recently.

MESSRS. KAYLENE, LTD.

DEAR SIRS,

I am in receipt of your sample of Kaylene, for which I thank you. I do not dispense and do not wish to be without some in the house.

My last sample was used on a patient suffering from acute Ptomaine poisoning following a meal of shell fish (mussel) at 10.30 p.m. Symptoms first appeared at 12.30 a.m., and when I saw him at 3.0 a.m. he was vomiting blood and passing almost pure blood per rectum. He had commenced cramps and nervous twitchings which would shortly have gone on to tonic convulsions. He was very collapsed and had a weak pulse. I gave him **only** Kaylene in cold water, one drachm every quarter of an hour, from 3.0 until 8.0 a.m., when I felt it safe to leave him. For the next two days Kaylene was given every one to two hours, and was then followed by Kaylene-ol. No other medication of any sort was used, and he made an excellent recovery. This follows a somewhat similar case which I treated at the end of last year.

Your excellent preparation should supplant Bismuth for any purpose.

Yours faithfully,

Physician to ———. ———, M.B.

Literature and supply for clinical trial obtainable from the manufacturers.

An Improved Method of Administering Pancreatin

Panteric Tablets

ENTERIC-COATED TABLETS EACH CONTAINING 5 GRAINS OF TRIPLE-STRENGTH PANCREATIN

IN order to make effective the oral administration of pancreatin, it is necessary to exhibit it in tablets capable of resisting the inactivating effect of the gastric juice. Parke, Davis & Co. have succeeded in perfecting a coating which contains no salol and is therapeutically inert, yet is able to prevent the disintegration of the tablet in the stomach and permit the liberation of the pancreatin in the intestine, where alkaline secretion provides the optimum condition for its action.

Pancreatin tablets so coated are issued under the name "Panteric Tablets". They are indicated for the relief of symptoms consequent upon incomplete digestion of proteins, also in diabetes (as an adjunct to insulin treatment) in food asthmas and urticarias, in tuberculosis, and in fermentative colitis.

Panteric Tablets are supplied in bottles of 25 and 100. A booklet giving full particulars of their therapeutic uses will be sent on request.

CLINICAL METHODS

By ROBERT HUTCHISON, M.D.Edin., F.R.C.P.Lond., and DONALD HUNTER, M.D., F.R.C.P.Lond.

For the Ninth Edition this Manual, now in its 87th thousand, has been thoroughly revised by Dr. Hutchison, with the collaboration of Dr. Donald Hunter, whose name replaces that of the late Dr. Rainy on the title-page. Help has also been given in special sections by recognized authorities on the subjects.

The illustrations have been reinforced by four new Plates, two of them in colour, and by some new Figures in the Text.

Secretary: N. RUTHERFORD WATSON

Affords relief in all cases of high blood pressure

The daily exhibition of Sal Hepatica, the non-habit forming saline purgative, has proved of extreme benefit in all cases of high-blood pressure. ¶ Sal Hepatica is also recommended as a rapid means of relieving the stress in cases of dysmenorrhœa. One or two drachms administered on the morning before the expected period, and again at its outset, rarely fails to relieve both the pain and depression. ¶ In chronic constipation the regular exhibition of Sal Hepatica for a week or two restores the daily habit of defecation. ¶ Sal Hepatica is not a "patent medicine" and is only advertised to the medical profession.

"Sal Hepatica"

KEROL CAPSULES

CREMOR ALKALINUS 'A. & H.'

Presents in a convenient and effective form the powders recommended by Professor MacLean for the intensive alkaline treatment of duodenal and gastric ulcers. Cremor Alkalinus "A" is the standard formula; where it proves to be too laxative in effect, formula "B" may be employed. In formula "K" the bismuth carbonate is replaced by colloidal kaolin, which possesses marked toxin-adsorbing properties.

The Relief of "Rheumatic" Pains

Dr. Guntzburg, the Medical Superintendent of the Physictherapeutic Institute of Antwerp, states that in practically all so-called "rheumatic" cases a pronounced degree of peripheral circulatory failure is symptomatic; and he says that the skin condition is "the immediate factor in the production of rheumatic pains." This is in accord with the emphasis laid at the recent Bath Conference on the part played by damp and cold in promoting neuritis and fibrositis.

Thermogene relieves pain by hastening the skin circulation, and so helping the removal of irritating waste products and the re-oxygenation of de-oxydised tissues.

The time to use Thermogene is when the very first twinge is felt. By its timely employment many an attack may be warded off.

Thermogene is a carefully prepared pure cotton wadding, remarkably soft and fleecy, freed from dust and other impurities, and impregnated with skin-stimulating vegetable essences.

A full-size box of Thermogene, with an interesting booklet on Surface Therapy, will be sent FREE to any medical man who is unfamiliar with Thermogene and its many uses in practice. The Thermogene Co., Ltd., Queen's Road, Hayward's Heath, Sussex.

Dimol

in Enteric Epidemicity

Causation is always difficult, and often impossible, to discover, but it seems a reasonable procedure, in epidemic areas, to assist prevention by the use of an intestinal bactericide. Dimol is non-toxic to any part of the alimentary mucosa, yet one grain has a bactericidal potency for cultures of B. typhosus equal to thirty-five times that weight of pure phenol.

The Dimol Laboratories are prepared to demonstrate to any properly constituted committee of the Medical Profession that a pure culture of this bacillus can be swallowed, and the germs destroyed in the stomach by the action of Dimol pulverettes, taken immediately after the culture.

The efficiency of Dimol in the treatment of many other intestinal conditions of bacterial origin is conclusively told in the interesting clinical reports which, together with a brochure dealing with the pathological significance of the intestinal toxæmias, will be sent to any physician on application to—

THE NATURAL MINERAL WATERS OF

CARLSBAD

Sprudel, Muhlbrunnen, and Schlossbrunnen

These waters act:

(1) By immediate contact with the mucous membrane of the stomach and alimentary canal, allaying pains and spasms in these organs, and stimulating the digestive organs into activity.

(2) Through the blood. That is, they change its condition by increasing the proportion of alkali in the blood as well as in all derivative secretions (gall, urine, etc.).

Largely prescribed in cases of

Chronic Gastric Catarrh, Hyperaemia of the Liver, Diabetes, Gout, Gall-stones, Renal Calculi, Diseases of the Spleen, and of the Kidney and Urinary organs.

Bottled under Official Supervision at Carlsbad and regularly imported by the Sole Agents:

INGRAM & ROYLE, Ltd.,

BANGOR WHARF, 45, BELVEDERE ROAD, LONDON, S.E.1.
And at LIVERPOOL and BRISTOL.

OVALTINE

BEFORE AND AFTER OPERATION

As a diet preparatory to surgical operation "Ovaltine" possesses unique advantages. It tends to keep the metabolism of the patient as nearly normal as possible. It also avoids a long period of starvation prior to operation, consequent irritation of the stomach by the gastric flow, and predisposition to greater irritation from the anæsthetic.

"Ovaltine" provides a means of nourishing the patient three or four hours before operation. It is almost completely absorbed, and therefore the stomach and intestines are empty at the time the operation is conducted.

"Ovaltine" lessens the predisposition to shock and counteracts the tendency to acidosis common after chloroform and ether anæsthetics.

In the usual processes of post-operative feeding by easy stages, from sips of water to the regular diet, "Ovaltine," by reason of its delightful palatability, ready digestibility, and high nourishing power, is ideally adapted.

A liberal supply for clinical trial sent free on request.

Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constitutents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

WRIGHT, LAYMAN & UMNEY LTD., 66, Park Street, Southwark, S.E.1

Calcium Deficiency in Expectant & Nursing Mothers

Pregnancy and lactation often produce manifestations of calcium deficiency because the calcium reserve cannot meet the demands made upon it. The systematic use of Kalzana in these cases stays the destructive processes in the teeth and bones of the mother, and ensures normal development of the skeletal structure of the infant. The special feature of Kalzana is that it combines calcium lactate and sodium lactate in the form of a double salt, with the result that the sodium element improves the blood alkalinity to the extent necessary to ensure adequate calcium retention.

"The Practitioner" says:

"Kalzana acts efficiently in promoting the growth of strong bones and healthy teeth, in protecting the expectant and nursing mother against a dangerous loss of calcium . . . . particularly because Kalzana promotes calcium retention."

Dispensed by Chemists in air-tight packets containing 50 and 100 tablets.

Kalzana

calcium-sodium-lactate

Also supplied *direct* for Doctor's own dispensing at 15/- per 1000 plain tablets.

R AND C

Specially indicated in

NEPHRITIS - URÆMIA - ECLAMPSIA - ALBUMINURIA

and allied conditions.

PROMPT and [illegible] diagnosis of kidney conditions [illegible] types [illegible] the administration of a specific capable of producing real results in compensating for the loss of kidney function is also necessary.

For more than a quarter of a century Nephritin has been a sheet anchor to physicians in treating such disorders. Nephtitin Tablets induce a marked increase in nitrogenous waste elimination. They reactivate the cells of the kidney, increase urinary secretion, and induce a greater output of urea.

Given in sufficient dosage these tablets produce marked results, and restoration to normal is quickly stimulated. They are invaluable also as a prophylactic in renal complications of infectious diseases and during pregnancy. The tablets are composed of the hormones of the normal kidney as they appear in nature—*absolutely unaltered.*

The Treatment of Influenza

with

S. U. P. 36

A recent article (*B.M.J.*, Oct. 12th, 1929, p. 663) containing some interesting clinical reports on the treatment of influenza with S.U.P. 36 has stimulated interest in this chemotherapeutic product. Subsequent publications (*B.M.J.*, Oct. 19th, pp. 738-739, Oct. 26th, p. 785, Nov. 2nd, p. 831) have revealed the fact that many physicians have been administering S.U.P. 36 constantly, as a routine measure in influenza and other acute inflammatory conditions, since its introduction some five years ago—a sure proof of its efficacy.

From the data published by the author of the above-mentioned article, it would appear that the administration of S.U.P. 36, if generally adopted, might result in a striking improvement in national efficiency. Actual figures show that out of 60 influenza patients the 30 who received treatment with S.U.P. 36 were detained from work for 255 days fewer than the 30 who did not receive such treatment.

Local Anæsthesia in Surgical Practice

CHRONIC ABSCESS OF RIGHT TIBIA.

TYPICAL CASE.

Mrs. N. S. D., aged 29 years.

Diagnosis: Chronic osteomyelitis (bone abscess) of the right tibia.

Operation: Channeling excision of necrotic tissue and introduction of Beck skinflaps.

Anæsthesia: Circumferential infiltration block (90 c.c. of 1 per cent. Novocain-Adrenaline solution).

Technique of Anæsthesia: 90 c.c. of Novocain-Adrenaline solution was introduced circumferentially—the needle passing laterally and posteriorly to the tibia just below the knee-joint. A small discharging sinus was excised, the periosteum elevated, and a channel cut by means of the mallet and gouge, removing approximately one-third of the circumference of the tibia. A number of chisel points were broken because of the eburnation of the bone. The endosteum was found to be sensitive, but thorough curettage was made. Pedicle flaps were turned in on each side and good results followed.

—Extract from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Vita-Weat contains every part of the wheat berry

When a diet regime is prescribed it is usual to include Vita-Weat, the British *wholewheat crispbread, in place of soft wholemeal* or white bread.

Vita-Weat is an article of diet combining the nutritive and health-giving properties of the best wholemeal bread with the palatability of the white loaf, at the same time ensuring an easily digested product with a high Vitamin, Caloric, and Protein content.

It is an all-British crispbread, guaranteed to be made from 100 per cent. stone-ground whole-wheat grown within the Empire. It is of distinctive texture, inviting mastication and insalivation; it has a delicious "crunchiness" and a pleasing ripe-corn flavour; and *it contains every part of the wheat berry*, nothing whatever being removed in the process of manufacture.

Not the least of the many benefits to be obtained from a regular diet of Vita-Weat is that of intestinal correction and the prevention of many of the intestinal and gastro-intestinal ailments due to constipation.

When forming a suitable proportion of the daily diet, Vita-Weat acts as a stimulant to normal peristalsis, whilst not exerting an undue irritative effect on the intestinal mucous membrane.

NATURALLY RICH IN VITAMIN 'D'

"SMILER"

A MILK FALLACY.

The inadequacy of cow's milk as a food for the infant is now accepted as a general statement of fact. Intended as it was by Nature to suit the digestive tract of the calf, it is not to be wondered at that its application to the feeding of the human infant leads in so many cases to unsatisfactory results. Modern research has definitely shown that its high buffer value, its cheesy indigestible curd, its varying composition, all render it unsuited to the digestive apparatus of the young child.

Apart from this, raw cow's milk, although in itself a most valuable food, has rightly received the almost unanimous condemnation of the Medical Profession in as far as its use for infants is concerned, owing to the grave risk of contamination with pathogenic organisms either at its source or during handling.

Cow & Gate Milk Food

"Cow's Milk made safe and suitable for Baby."

Science has, however, come to the aid of practice in the shape of the Cow & Gate Improved Roller Process of drying, embodying every care and control known to-day, by which, without the loss of a single essential quality, a transformation is effected which annuls the dangers and deficencies of raw cow's milk, and produces a milk which tests and experience of over a quarter of a century have proved to be the only safe and reliable milk food for the artificial feeding of infants.

The makers will gladly supply samples for Clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

BROKEN LID OF A BOX WITH THE INSCRIPTION "MEDICINE CHEST BELONGING TO THE HSIEN-MING COMPANY"

The medicine chest cover here reproduced was found upon the site of an ancient Chinese military station. Ginger, cinnamon, rhubarb and ginseng (this last was considered a great panacea and worth three times its weight in gold) were among the drugs most frequently employed by the ancient Chinese physicians. They believed that nature held a remedy for every ailment and this led to a vast amount of experimenting with vegetable, animal and mineral substances, with the object of adding to their materia medica. When we realise that Chinese pathology takes account of 10,000 varieties of fever and fourteen kinds of dysentery, we are not surprised to learn that no other nation possesses so many medicaments. Among other medicaments in very common use in ancient China may be mentioned camphor, which was employed as a diaphoretic, carminative, sedative, anthelmintic and anti-rheumatic (as well as for aching teeth and perspiring feet); cannabis, prescribed in nervous and many other disorders; and aconite, which was administered in a very wide variety of disorders. Even in those days iron was used for anæmia. Pomegranate root was found useful in treating for worms; arsenic was employed in malaria; mercury and sulphur in skin diseases. Emetics were composed of the sulphates of soda and copper.

ARTHRITIS.
AMBULATORY TREATMENT.

Mobility and freedom from pain in crippling arthritis of the hip and knee even after shortening and contracture have occurred.

This is the special achievement of BELLE VUE SPA; secured by Hoefftcke's extension appliances, which maintain continuous extension by night and by day.

The appliance permits the patient to walk, and not only takes the body weight but replaces the normal state of compression of the leg by one of active stretching.

There is no other satisfactory way of combining movement with extension.

The method secures:

1. Extension without muscle loss inevitable when the patient is kept in bed.
2. Extension without the vascular stasis which occurs when a joint is kept at rest,

AND

MOVEMENT WITHOUT PAIN.

The result is rapid reconstruction of the joint with astounding restoration of function in those advanced cases which have hitherto seemed hopeless and incurable.

BELLE VUE SPA is well equipped for auxiliary treatment by massage, electricity, diet, light, etc., and full advantage is taken of the tonic virtues of its chalybeate waters.

LUPUS VULGARIS:
A PLEA FOR EARLY AND ORGANIZED TREATMENT.*

BY

RUPERT HALLAM, M.D.,

PHYSICIAN IN CHARGE OF THE SKIN DEPARTMENT, ROYAL INFIRMARY, SHEFFIELD.

COINCIDENTLY with other Northern European countries, Britain has a considerable number of its inhabitants who suffer from tuberculous infections of the skin. When compared with other skin infections the incidence of lupus vulgaris is low, but the extreme chronicity, the tendency to spread, and the unsightliness of its ravages make the disease, as its name implies, particularly abhorrent to all. Essentially a disease of poverty, a factor which handicaps severely any effort to assist the unfortunate sufferers, the complaint presents at the present time almost insuperable difficulties to those who are responsible for its treatment.

At the time of a reorganization of hospital service in this country it does not appear inopportune to consider whether any further effort can profitably be made to mitigate the difficulty. The first point to determine is whether efficient remedies do exist, and if so, secondly, to what extent they are available for the patients. It is outside the scope of this paper to give a detailed description of the modern methods of treating lupus vulgaris, but a brief review of the subject is necessary if the difficulties of the situation are to be appreciated.

It is clear from the pathology of the complaint that it is not a superficial disease. Sampson Handley and others have pointed out that it is a disease of the lymphatics, not limited to the skin, for both the superficial fat and the deep fascia are implicated, except in the very earliest lesions. The infection may be exogenous in origin; in that case the bacillus is implanted directly on to the skin—for example, lupus on the fingers or hand, which is met with occasionally in pathologists, farmers, and butchers—or, more frequently, is conveyed to the mucous membrane of the nose by the fingers, which have been contaminated by infected dust. The second mode of infection is by continuity from bone or gland, or by the blood stream. The resistance of the patient against the infection is often low, for, as previously pointed out, lupus vulgaris is a disease of the poor.

All are agreed, no matter where the site of the lesion may be, that treatment in the early stage is of paramount importance; also, that there is no single remedy which may be relied upon to effect a cure in all cases. A further difficulty is the fact that few, if any, are sufficiently expert to be able to give the appropriate treatment to every class of case. As an instance, an examination of the nose and mouth by a competent rhinologist will reveal that a large proportion (probably 50 per cent.) have some tuberculous infiltration of the mucous membrane. This is mentioned in most textbooks, nevertheless the examination is frequently dispensed with. Yet mucous membrane lesions call for treatment equally with those which are present on the skin. If they are not treated they are a constant source of reinfection of the skin. Again, it is an advantage for the patient, and also for economic reasons, that some of the earlier lesions should be excised by an experienced surgeon. This applies particularly to patients who are unable to attend regularly for the long periods necessitated by the other methods of treatment, such as Finsen light, caustics, etc.

Excision of patches of lupus, with or without subsequent skin grafting, was advocated many years ago by Lang of Vienna, who attained great proficiency in this branch of surgery. It has been practised by Sampson Handley and other surgeons in this country, and also by Thibaut in France. Recent experience has convinced me that excision is the method of choice in many early lesions, but unfortunately patients usually apply for treatment when the disease has advanced beyond this stage; consequently it is necessary to have recourse to other methods, such as diathermy, Finsen light, Kromayer light, various caustic applications, etc. Furthermore, each case must be treated individually. Some patches will heal after repeated application of acid nitrate of mercury, others will not, and require destruction by diathermy. Local application of Finsen light is a proved remedy, and it is regrettable that such a limited use is made of it in this country, for in selected cases the result of the treatment is admirable. It is generally stated that the method is impracticable on the ground of expense, yet with a Finsen-Reyn lamp costing from £160 to £200 to install, about ten patients can be treated daily. The application requires, however, the whole attention of a specially trained nurse.

In addition to the remedies already mentioned it is essential that all patients should have the advantage of frequent exposures of carbon arc light to the whole skin surface. After six years' experience of this treatment in a large number of cases I have no hesitation in asserting that it is indispensable in the treatment of tuberculosis of the skin. At the same time I find it necessary to state equally dogmatically that general arc light exposures must not be relied upon to cure patients without the help of local treatment. In the summer months advantage may be taken of the natural sunlight. Three years ago arrangements were made whereby the lupus patients in the Royal Infirmary, Sheffield, could attend, when weather permitted, various centres in the neighbourhood for exposure to sunlight. The necessities, such as screens, deck chairs, rugs, and lavatory accommodation, were obtained conveniently in the grounds of the tuberculosis sanatoriums, convalescent homes, and municipal hospitals outside the city. This out-of-doors treatment educates the patients to appreciate the advantage of open air and sunlight. They enjoy the change, become much more deeply bronzed than when exposed to artificial light, and the results are also superior.

The merits of gold preparations, tuberculin injections, and sundry other remedies I do not propose to discuss. It is sufficiently obvious that the armamentarium of those who are responsible for the treatment of the disease is necessarily extensive and costly. Also, that it is available for only a fraction of the number who suffer from the disease. This accounts in no small measure for the number of hopelessly infected patients who seek relief sporadically at the out-patient departments of our hospitals.

An equally important factor is the delay which ensues before treatment is sought. This is due largely to the following reasons: mistakes in diagnosis; the application of futile remedies such as ointments and fomentations; the apathy of the patients or their parents. The disease is painless, the patients are poor, and all too frequently incline to a policy of *laissez-faire*. On the other hand, some are anxious for treatment, but are not able to afford the time off work or the necessary travelling expenses. This delay leads to serious consequences, for the lesions gradually increase in depth and at the periphery. The time required for the treatment is thus not only proportionately greater, but also more costly. Many of these neglected cases attend the out-patient departments of the voluntary hospitals for periods of years. This entails much expenditure of time and patience of the nursing and medical staff.

From the age of 6 to 14 a child undergoes a systematic medical inspection at school, and afterwards, no matter how poor, has the opportunity of obtaining medical advice: but, as the following analysis of cases attending the Royal Infirmary, Sheffield, shows, the present conditions are deplorable.

Analysis of 211 Cases of Lupus Vulgaris attending for Treatment during Three Years—May, 1926, to May, 1929.

Sex:	
Males	73
Females	70
Location:	
Residing within the borough of Sheffield	75
,, within 10 miles of Sheffield	29
,, between 10 and 20 miles outside Sheffield	31
,, between 20 and 30 miles outside Sheffield	5
,, beyond 30 miles outside Sheffield	2

* Read in the Section of Dermatology at the Annual Meeting of the British Medical Association, Manchester, 1929.

This analysis indicates that almost half the total number of patients live outside the city, consequently regular attendance for treatment is in many cases prohibitive owing to the travelling expense.

Age of Patients.

Decade.	Number.
1-10	18
10-20	61
20-30	27
30-40	19
40-50	8
50-60	4
Over 60	3

In the following table an attempt has been made to classify the cases according to the extent of the disease present when the patient first applied for treatment.

1. A stage in which there was a reasonable hope of a cure being accomplished	31
2. A stage in which the prospects of a cure were doubtful but perhaps possible under good conditions	85
3. A stage in which a cure was impossible	19
Unclassified	5

It indicates that more than half the patients apply for treatment when the disease is already in an advanced stage.

Duration of the Disease on Admission of Patients for Treatment.	No	Patients who had either no Treatment or only Ointment before Admission	Treatment by Caustics before Admission.	Surgical, Diathermy, Light, X Rays before Admission.	No Record.

Totals ...	143	72	5	34	22

It will be noted from the figures in the first two columns of this table that a large number of patients applied for treatment years after the commencement of the disease, without having had any treatment in the interval.

It is hardly necessary to stress the suffering which many of the patients endure, for every dermatologist is only too familiar with the terrible disfiguration of the face and limbs which may result from the spread of the disease. To many of the lay public the disease exists only in name, for lupus patients have difficulty in obtaining employment, and, conscious of the unsightliness of their deformity, are prone to seek seclusion.

For economic reasons it is desirable that all patients should be treated by the best available methods as soon as the disease is recognizable. To further this end I have ventured to put forward the following suggestions, which for convenience I shall deal with under the following headings: (1) education of the medical and lay public; (2) establishment of treatment centres; and (3) systematic following up of cases.

Education of the Medical and Lay Public.

Taking into consideration the abundance of material available for teaching purposes and the consistency in the appearance of the tuberculous lesions of the skin, there appears to be no adequate reason why the diagnosis should present any great difficulty. It does not seem to be too much to expect that every senior student should be able to recognize tuberculosis of the skin in the early stages, and, furthermore, that he should know the seriousness of the consequences if it be untreated. The increasing popularity of post-graduate instruction will no doubt tend to reduce such errors.

If practitioners and school medical officers consistently explain to the patients, or to their parents in the case of children, the disastrous results of neglected treatment, the public are likely to follow their advice, provided that facilities for treatment are obtainable.

Establishment of Treatment Centres.

The foundation of a special treatment centre similar to the world-famed Finsen Institute at Copenhagen would be of inestimable value to this country. Although one centre would be able to cope with only a limited number of cases, it would serve a further important purpose in acting as a stimulus to those who are interested in the treatment of the complaint; for new methods could be tried out systematically, approved treatment could be demonstrated, and advice given on the organization of smaller centres. Such an institute would naturally require to be well equipped and have an adequate staff, in order to enable a high standard of treatment to be carried out. In view of the complexity of the treatment, the building should preferably be attached to, or within easy reach of, one of the larger hospitals, in order that advantage might be taken of the services of the consultant staff. A few beds would be required for the use of patients undergoing operative treatment, but the ideal would not be attained unless there was, in addition, an annexe of, say, 100 beds situated either in the country or at the seaside, where part of the treatment would be carried out. The annexe would be constructed and maintained on the lines of a convalescent home; the cost per bed would therefore be considerably less than in the case of a general hospital. Again, as the patients would not be confined to bed, they could be employed advantageously in doing domestic work, gardening, and poultry farming, thus reducing the expenses still further. It is probable that the beds would be used more profitably if a relatively large number of patients had short spells of six to twelve weeks' institutional treatment, rather than if a comparatively small number monopolized them for long periods. If the annexe contained the number of beds suggested—that is, 100—it would, in addition, enable patients from smaller affiliated centres to have the advantage of convalescent treatment. Preference would, however, in all circumstances have to be given to cases in which there was a reasonable chance of a cure being obtained.

As already stated, an institution of this character could only deal with a small proportion of the cases in the country, but, in addition, it would serve equally important functions. If after a trial these anticipations were fulfilled, it would then be desirable to consider whether a more comprehensive scheme should be attempted—namely, an increase in number of these special lupus institutes, together with the formation of subcentres at some of the voluntary and municipal hospitals—and thus enable all cases of lupus, unless already too far advanced, to have a reasonable chance of being cured. Many of the larger voluntary hospitals are already more or less completely equipped for the treatment, and with an increase of staff could extend the service and give further facilities, such as evening clinics, for those employed during the daytime.

Systematic Following Up of Cases.

Although the majority of patients are anxious to avail themselves of treatment, others, usually for economic reasons, are irregular in their attendance; consequently no scheme of organized treatment would be complete unless travelling expenses were afforded to necessitous cases.

Added to which there should be a systematic following up of patients to encourage the delinquents, and also to ensure the early detection of any recurrent lesions.

In conclusion, I beg to point out that an admirable organization for the treatment of venereal disease already exists under the aegis of the Ministry of Health. That movement rescued this branch of medicine from the realms of chaos, and has proved of great service to the community. It seems justifiable, therefore, to ask that equal facilities should be given to a class of patients who are at least equally worthy of consideration.

DIFFERENT PREPARATIONS OF BISMUTH IN SYPHILIS THERAPY:

RATE OF ABSORPTION AS A GUIDE TO THEIR EMPLOYMENT.*

BY

SVEND LOMHOLT, M.D.,

COPENHAGEN.

BISMUTH is already adopted, only eight years after its introduction into syphilis therapy, by practically all syphilologists throughout the world as a substitute superior to mercury. It is obviously both more efficient and less toxic than this old remedy. Still there remain a few exceptions to this rule. Bismuth can be administered by intramuscular injection alone, as it is absorbed to a very small extent only through the skin and through the intestine. For these methods of administration resort must still be had to mercury. This rapid development of bismuth therapy has brought many hundreds of preparations on the market; it is therefore not easy for the doctor to make a right choice.

The following investigation is not intended to be an examination of a series of factory preparations, but merely a general outline, according to which the proper choice can be made.

Very little is known with regard to the characteristics of bismuth in its effects on a syphilitic organism and the syphilitic infection itself. The blood contains only very small quantities of bismuth (Levaditi et alii,[1 2] Sei and Weise,[18] Lomholt,[4 7 8 9] Biro Istvan,[10] Levy and Selter,[21] Gruhzit and Sultzaberger,[13] Leonard[14 15 16]), probably so small that we can disregard a possible direct effect on the spirochaetes similar to that generally produced by disinfecting solutions of heavy metals *in vitro*. Levaditi[1 2] has tried to give a specific explanation of this strong effect on the spirochaetes. He suspects the formation of a special compound of bismuth and the protein substances of the organism ("bismoxyl"). He thinks that this compound possesses a particularly strong effect on the spirochaetes.

Though nothing definite is known about the characteristics of bismuth in its effects on the syphilitic infection, it is a well-established fact—obtained from clinical experience as well as from experiments on rabbits with syphilis—that a complete cure is attained only after a prolonged course of bismuth therapy. The best effect is obtained when large quantities of bismuth are introduced, creating a strong bismuth concentration in the organism. Of course, the concentration should never reach the point of intoxication, as this would only weaken the organism. Consequently the aim of the bismuth treatment must be to introduce into the organism the largest possible quantities without intoxication, maintaining thereby a strong saturation over a long period. Under bismuth treatment proper attention should be given to the fact that elimination of the metal is rather slow; consequently an intensive introduction of bismuth causes a rapid accumulation of the metal in the organism, and if continued for a long period will result in an intoxication.

Intensive bismuth treatment should not be continued very long. It may be borne well in the beginning, especially if the remedy used is one of slow absorption, but after some time the organism will be oversaturated and an intoxication will appear. This fact is to be taken into account in planning the scheme of treatment. The old scheme of intermittent treatment (Fournier) permits the use of larger doses than does the continuous method without interruption, proposed by some modern authors. The intermittent scheme has given undeniably excellent results, and its rhythmic character may be considered to agree well with the rhythm of vital processes. The essential thing in all bismuth treatment must be to secure a uniform and regular absorption. Otherwise a sudden strong absorption may bring a dangerous intoxication; or, on the contrary, a lack of absorption may cause a deficiency of the therapeutic effect. For this very reason the internal and percutaneous administration of bismuth must be left out of the question. Ointments may give an absorption of bismuth, but this is always weak and very irregular (Klauder,[19] Oelze,[20] Giemsa,[21] Engelhardt[36]). Applied on injured skin bismuth may be absorbed to quite a large extent—a fact well known since ancient times from the treatment of extensive burns with bismuth ointments. Even fatal accidents have occurred. Internal administration produces also a very weak absorption (Engelhardt[36]), probably due to the fact that insoluble BiOCl is formed in the stomach, owing to the effect of HCl upon the bismuth compound in question. If no HCl is present, but only organic acids such as lactic acid, complex compounds of bismuth may be formed and absorbed in the same way as the many alkaline bismuth tartrates used in bismuth therapy from its very beginning (Levaditi,[1] Gérard and Daunic,[22] Perrin and Ducas[23]). Consequently bismuth must be used in the form of injections.

The *intravenous* injection gives decidedly the quickest and most regular absorption, but clinical experience has shown that it is rather dangerous, several cases of death having been reported. Besides, it is not especially efficient. The bismuth injected leaves the blood stream quickly. Sei and Weise[18] found in rabbits that after one hour the bismuth content in the blood was reduced from 11.5 mg. per 100 c.cm. to 0.17 mg. Accordingly the elimination was found by most authors (Jeanselme,[29] Engelhardt[36]) to set in and increase quickly, to reach its maximum and fall to a minimum again in rather a short time. In consequence of this rapid passage of bismuth frequent injections are necessary, preferably every day, which makes this treatment rather troublesome. Besides, the treatment gives rise to a particular strong neuralgia in the trigeminal nerve, which occurs immediately after the injection. Intravenous treatment has now been given up even by its original adherents (Pautrier).

Subcutaneous injection cannot be recommended. It causes greater pain than the intramuscular method, and abscesses occur more frequently; also the absorption is slower and more irregular.

Intramuscular injection remains the treatment to be preferred. The single injections should be given in the upper and outer part of the gluteal muscle. The number of preparations made for this purpose is most embarrassing, and it must be admitted that it is possible to obtain quite good results with practically all of them. At a very early date Levaditi[1] pointed out that even quite small quantities of bismuth were able to give a marked antisyphilitic effect. But this is not the same as a maximum effect, and our aim must always be to find just that preparation and that method of treatment which secures the very best result to the patients. The investigation of these problems is simplified by the fact that the antisyphilitic effect is due to the bismuth ion itself—or rather to the bismuthyl ion. As regards the different bismuth preparations, their bismuth metallic content is alone of importance. However, an exception is provided by certain bismuth compounds, in which the bismuth is bound so firmly that the organism is unable to dissociate it (for example, triphenylbismuth, Giemsa[26]). With these the therapeutic effect will prove to be less than would otherwise be expected. The essential thing must always be to have a preparation with an absolutely regular and uniform absorption rate. These two things depend to a large extent on another quality—that of the rate of absorption.

If a certain quantity of bismuth is injected into a muscle, and if it is not absorbed immediately, the surrounding

* Read in opening a discussion in the Section of Venereal Diseases at the Annual Meeting of the British Medical Association, Manchester, 1929.

tissue will soon begin to encapsulate it, and from the moment this occurs the rate of absorption will be seen to decrease markedly. Sometimes the bismuth deposit may remain for a long time almost untouched, like a foreign body—that is, if the muscle has had time to produce a sufficiently thick, compact capsule around the deposit. In such a case only an extremely slow absorption will take place, and the therapeutic effect will be accordingly insignificant. In the days immediately following an injection there will as a rule be ample absorption of bismuth from the newly injured surface of the muscular tissue; later the absorption will gradually decrease. Consequently a slow absorption generally means an incomplete absorption, a certain portion of the injected metal remaining encapsulated for an indefinite period. An *x*-ray photograph of the nates with bismuth deposits will often show a great many shadows due to the encapsulated material. This was confirmed by a large number of authors. (Levy-Bing,[27] Kolle,[28] Beinhauer and Jacob,[29] Sonnenberg,[30] Cole, Farmer, and Miskdijan,[31] Oettinger, Todd, and Sollman[32].)

Still the *x* ray is not an ideal method for control in these cases. Small precipitates of chalk often appear around the deposits, the shadow of which may closely resemble that of a bismuth shadow (Müller,[33] Jaffe,[34] Gruhzit[35]).

By experiments on animals, where the injected deposits of bismuth can be excised, one can see still more distinctly how great the differences are, and especially with bismuth in oil suspension (Lomholt[5 8 9]). On the other hand, a single injection is seldom given, but generally a series. By this the irregularity in the rate of absorption in the single deposit will to some extent be compensated.

To the question as to the kind of bismuth preparation which is absorbed most rapidly and regularly after intramuscular injections the answer must be: watery solutions. This emerges clearly from all researches of bismuth elimination after such injections (Lomholt,[5 6 8] Leonard,[11] Gruhzit,[13] Engelhardt[36]). However, it appears that even small doses cause a certain amount of pain. Consequently it proves necessary to give the injections rather frequently —for example, every other day—to obtain a suitable weekly dose of bismuth, and even then pain cannot be avoided. Gruhzit[13] attributes a relative absence of pain to thiobismol, a sodiumbismuthoglycollate, a compound first studied by Akamatsu.[37] My experience, however, is that this is not quite painless. It must, at any rate, be given three times a week. It is, therefore, impracticable as the intravenous treatment.

Instead of watery solutions, solutions of bismuth compounds in oil have been employed—for example, bismuth salts of high atomic fatty acids. They are fairly soluble in vegetable oils. At an early date Merck brought forward "embial." The exact composition of this has never been published. Further, a number of French preparations have lately been recommended by Levaditi[38] and his collaborator, L. Fournier[39]: basic α-carboxethyl-β-methyl-nonoate of bismuth, basic α-methyl-hydrocinnamate of bismuth, camphocarbonate of bismuth, etc. The clinical effect of these preparations is reported as extremely satisfactory and quite painless. I have not been able to confirm this last point, but the pain is certainly not very bad. A considerable amount of material is, however, necessary before the clinical superiority of a particular remedy can be admitted. It would certainly be a great advantage if these oil solutions combined a relative painlessness with an especially great rate of absorption and regularity. Levaditi[38] (p. 598) found this, but unfortunately his researches are not extensive. As to "embial," Engelhardt[36] (p. 31) found no especially quick absorption. Similar observations were made by Grumach,[40] who did not find substantial differences between oil solutions and the usual oil suspensions. This fact corresponds fairly well with Levaditi's[38] (p. 600) statement that even after twenty-four hours a decomposition of the compound takes place, a definite bismuth deposit being formed in the muscle, which can be traced for a long time. Levaditi thinks that the bismuth is deposited in the form of oxide or oxychloride; but if this is the case there should be little difference between the condition in the muscle whether injected by this compound or by others, suspended in oil. A definite inconvenience with these preparations is the presence of large quantities of vegetable oils and of high atomic fatty acids, which are only with great difficulty absorbed by the tissue.

The form in which bismuth is most commonly used is that of suspensions in vegetable or vaseline oil. Such suspensions are almost painless. The oil covers the small suspended bismuth particles and prevents a rapid reaction between these and the surrounding tissue. How great the difference is was clearly seen from the following experiment with eight patients. A dose of 150 mg. bismuth salicylate suspended in vegetable oil was injected, and another, a week later, in water. The first was borne almost without any pain; the second caused considerable pain in most cases, and, moreover, in three cases a severe stomatitis appeared shortly after the injection. The explanation of this fact was quite clear. It is a well-known fact that the muscular tissue absorbs vegetable oil very slowly—not until after several months—and vaseline oil is not absorbed at all. Before the absorption of bismuth can take place the oil must be separated from the bismuth particles. With bismuth compounds soluble in water or in the tissue fluid a more rapid absorption can take place, but then it always causes pain. It must be said that as a rule it is scarcely possible to have a rapid absorption without a definite pain. This is easily understood. The absorption implies a reaction of the bismuth ion with the tissue. Hereby bismuth albuminates are formed and the tissue is more or less destroyed. If this takes place quickly, pain is inevitable, if slowly, no pain may occur. Even a considerable necrosis of the muscular tissue with abscess may develop without any noticeable pain. More often the tissue forms a capsule of granulation tissue round the injected deposit. The absorption remains imperfect, and will sometimes stop completely, especially with such bismuth compounds as are insoluble in water or in the body fluids.

All bismuth injections injure the muscular tissue in a definite way. The simplest form is a small necrosis, which is gradually replaced by granulation tissue that later on develops into a little scar. In patients who have received long series of bismuth injections it may happen that, in giving an injection, the needle may enter into such highly vascular granulation tissue, and blood will appear; or the needle will meet with strong fibrous resistance—that is, scar tissue. Injections should not be given in either of these cases; in the first, because of the risk of intravascular injection, in the second, because the fibrous scar tissue offers a most resistant barrier to absorption.

As mentioned before, the use of oil for suspension often causes a rather slow and irregular absorption of the contained bismuth. This hampering of the absorption is, however, not a rule without exceptions. In some cases a fair absorption can be seen even in these cases, but it cannot always be expected.

A large number of bismuth compounds have been used in oil suspension. In the composition of these preparations it seems as if the desire to secure an absolutely painless preparation has been the principal aim of both manufacturers and physicians. This seems to me a somewhat narrow point of view. A moderate amount of pain is not a definite drawback. It generally means that a good absorption is about to take place. Still, the pain must not be so great as to prevent the patient from doing his work and perhaps cause him to discontinue treatment.

The rate of absorption of the different bismuth compounds seems to correspond closely with their solubility in water. Most of the bismuth compounds used in syphilis therapy are generally characterized as "insoluble in water." Still, "insolubility" seldom means an absolute insolubility, but in most cases a very slow solubility only. As to the bismuth compounds in question, they are practically all slightly soluble in water, and especially if small quantities of albumin or sodium chloride are added to the water.

It seems practical to divide the various compounds into groups according to their rate of solubility. The carbonate, oxide, and oxychloride of bismuth, and metallic bismuth compose a definite group of very restricted solubility. Also they are absorbed very slowly. Few examinations have been made on this group of compounds, but they all point to a very slow absorption. Thus Biro Istvan[19] found that only 6 per cent. of bismuth was eliminated

in the urine and faeces in thirty days after a series of injections of, in all, 0.2 gram of metallic bismuth in a 10 per cent. suspension in oil ("sorbismol"). I made a few examinations on BiOCl.[8] In some of these a fairly quick absorption was found, but the reason for this was probably that an exceptionally weak suspension was used, and, moreover, that the doses of bismuth itself were so very small.

The next group comprises the hydroxide, the subnitrate, and the oleate of bismuth. These are not of quite so minimal a solubility as the above-mentioned. The elimination of the hydroxide was studied by me, and it was found that in two cases after fourteen days only 7.53 per cent. and 5.86 per cent. of the injected quantities was eliminated in the urine. Kürthy[17] found with bismuth oleate ("oleo-Bi," Roche) used in a dog that only 10 per cent. was eliminated in the urine during twenty-eight days. Leonard[16] found in rabbits that 5.66 per cent. and 10.60 per cent. was eliminated in fourteen days. Still these preparations are used to a large extent in therapy. Well-known preparations are "muthanol" (French), "casbis" (German), both hydroxides, "oleo-Bi" (Swiss). The dose generally recommended for these preparations seems rather large. The reason for this is obviously their slow absorption. Bruck[11] mentions a case where 1.5 grams of bismuth ("casbis") were given by a mistake instead of 0.15 gram. "In spite of observation for several months, not the slightest untoward consequences of this enormous dosage were shown by the patient." Such observations are rather condemnatory of the therapeutic effect of this sort of preparation. The death reported by Jörgen Munck[12] was caused by injections of bismuth hydroxide in oil suspension.

The third group comprises certain organic compounds. Bismuth iodoquinate is absorbed fairly quickly. I found that in two cases 12.85 per cent. and 20 per cent. was eliminated in the urine after fourteen days. Corresponding observations were made by Engelhardt[36] with a similar preparation (bismuto-yatren B). He found that 23.7 per cent. was eliminated in the twenty-three days that the treatment lasted, and that this rather strong elimination continued. Bismuth chloride and iodine has, however, a great drawback. It contains only 20 to 24 per cent. of bismuth. Large quantities of the preparation therefore must be injected. Moreover, the high content of quinine and iodine is liable to irritate the tissue. Infiltrations are often seen in the muscle tissue after the use of this remedy. The compound is used under various names: quinby, bijochin, vijochin, bijochinol, biquinyl, rubyl, etc.

Potassium-sodium-bismuth-tartrate was the very first preparation used in therapy by Levaditi under the name of "trépol." Sometimes it is absorbed fairly quickly, but sometimes rather slowly. The first statements of Levaditi are well known. He gave five injections to different rabbits. After one day 30 per cent. of the injected quantity was found to be absorbed, after six days 21 per cent., after thirteen days 23.5 per cent., after twenty days 17.1 per cent., and after twenty-five days 19.3 per cent. The scale of absorption turned out almost the opposite of what might have been expected. I found after two injections that 22.2 per cent. of the injected quantity was eliminated. Biro Istvan[10] found after injection of "bismuluol" (potassium-bismuth-tartrate in oil) that 16 per cent. was eliminated in six days. Leonard and O'Brien found with the same compound 26.30 per cent. and 42.24 per cent. eliminated in the urine during fourteen days.

Gruhzit, Tendick, and Sultzaberger found by examination of the deposits in dogs that about 46.7 per cent. of the injected bismuth was absorbed in eight days, and that the figure rose to 90.9 per cent. in three weeks. Still these figures are presumably rather high (see below). Cettingen, Todd, and Sollmann found in a single rabbit a very slow absorption. After 105 days only 30 per cent. was absorbed. The quantity given, 50 mg., was very high for a rabbit, but was tolerated

The conclusion from the above facts must be that this remedy as a rule is absorbed fairly quickly, but that there are numerous exceptions.

Bismuth salicylate is used to a very large extent, especially in America, England, and Germany. Probably it is the most commonly used of all bismuth compounds in therapy. Gruhzit, Tendick, and Sultzaberger have studied its absorption in dogs. The deposits were removed and examined. The average absorption was: 67.4 per cent. in eight days, 87.8 per cent. in fourteen days, and 94.8 per cent. in twenty-one days. The figures of elimination in urine are surprisingly smaller than might be expected from the above; thus in one case only 19.1 per cent. was eliminated during fifty-two days, in another only 13.9 per cent. in fifty-four days, in a third only 22.7 per cent. in twenty-four days, and in a fourth only 9 per cent. in thirty-eight days.

Prater[13] mentions a case where an extremely slow absorption of bismuth salicylate was noticed. By mistake a patient received in three days 1.2 grams of bismuth, which is an enormous overdose. After one week a moderate stomatitis appeared and a slight fever, but no serious signs of intoxication.

Summarizing, it may be said that all suspensions of bismuth in oil are absorbed somewhat slowly and irregularly. With the last group, potassium-sodium-bismuth-tartrate, iodoquinate of bismuth, and bismuth salicylate, this is least pronounced. Because of this fact I think that this last group should be preferred. The tartrate has the drawback of a somewhat varying composition and content of bismuth metal. The iodoquinate has a rather low bismuth percentage; large doses must therefore be given. Further, it irritates the tissue. The salicylate has no such drawbacks. Consequently I consider this compound to be the most suitable for use in oily suspension.

Still, as often emphasized above, the oil introduces a considerable factor of irregularity. Water, on the contrary, is absorbed immediately, and bismuth particles in watery suspension will therefore at once be brought into direct contact with the muscular tissue, and the best possible condition for a quick and regular suspension is created, especially so as a watery suspension is thin and spreads very easily among the fibrillae of the muscle. The rapid absorption will cause a certain increase of pain (see above under bismuth salicylate).

I made a series of comparative examinations to see what difference a change of suspension fluid would give as to the rate of absorption of two well-known compounds. The results were as follows: bismuth hydroxide in oil gave an elimination of 7.59 per cent. and 5.86 per cent. in fourteen days; bismuth hydroxide in water, 47.4 per cent. and 35.57 per cent.; bismuth iodoquinate in oil gave an elimination of 10.43 per cent. and 15.57 per cent., against 47.30 per cent. and 48.63 per cent. in water. For metallic bismuth in oil (sorbismol) Biro Istvan found an elimination of 6 per cent. in thirty days; for a watery suspension (néo-trépol) Leonard[16] an elimination of 19.20 per cent. in twenty-two days.

It is impossible simply to change from oil to water. This was seen clearly with bismuth salicylate. The pain would be too great, and might even prevent the patient working. A bismuth compound must be found that is less "soluble" and therefore of a slower reaction. The hydroxide proved to be in some ways fairly good, but it had the drawback that it was difficult to obtain a perfectly pure preparation with particles of a definite size. The oxychloride possesses obvious advantages on these two points. It is easy to prepare, is perfectly pure, and has particles of a quite homogeneous size. Moreover, it is less soluble than the hydroxide, and is well tolerated even in a watery suspension. If the particles are very small and the total surface of the bismuth compound correspondingly large, the absorption will be so sudden that it will certainly produce pain. This was the case if the particle had a size of 0.5 to 1 μ.

Experiments were made with particles of different sizes. A size of 3 to 5 μ proved to be suitable. A suspension of these was tolerated well by most patients, and if pains occurred they were mostly slight. The doses of this suspension can be fixed at a lower point than with oily suspensions: 20 cg. (= 170 mg. Bi) is a suitable dose for men; 15 cg. (= 125 mg. Bi) for women, given in series of eight to ten injections at intervals of five to seven days. This means an average dose of about 0.5 mg. per day per kilo of body weight during the course of treatment. After four or five

injections a thin blue line is generally seen along the edge of the gums. But this line is seen with all intensive bismuth treatment. It is simply an inevitable sign of a strong saturation of the organism. The interval between the series should be about six weeks. During this time the blue line will generally weaken, but seldom disappear entirely. The injections must be given in the usual place and manner. Special regard must be paid to the risk of an intravascular injection, as the fluid is rather thin. After the needle is put in, an aspiration must always be made before the injection, to ascertain that the needle is not placed inside a vein or an artery. But even if blood does not appear, the needle should be retracted slightly during the injection, because experience proves that even with a negative result of the aspiration test it may happen occasionally that the fluid is forced into the lumen of a vein or, still worse, of an artery. In the last case a serious infarct of the muscle and of the skin covering it may be the result (Freudenthal, Gammel). I have seen a few such arterial infarcts—fortunately not very serious—also during the use of the preparation mentioned here, but after the outlined scheme of injection was adopted it was not seen any more. If the opening of the needle should pass another vascular lumen during the retraction, insignificant quantities only can be pressed into it, because the needle is withdrawn slightly but continuously.

A factor of great importance in syphilis treatment, especially in the intermittent scheme, is the retention of bismuth in the organism. This is composed of two quite different parts: (1) the diffuse storage of bismuth in the different organs and tissues of the organism; and (2) the injected deposits. The latter have already been discussed above. The bismuth contained in them may amount to a large quantity, especially with preparations of slow absorption. Sometimes a continual, even stream of bismuth may be absorbed from these deposits over a long period, maintaining thereby a most useful antisyphilitic effect. Sometimes the stream flows most irregularly, and sometimes a compact encapsulation will stop all absorption. Large deposits represent a certain risk of intoxication, as a sudden strong absorption may occasionally, and quite unexpectedly, take place—for example, after unusual exercise. This risk must, however, not be overestimated, as these cases are by no means frequent.

The diffuse storage has been estimated quite differently by different authors. Gruhzit (loc. cit., p. 101) found in experiments with dogs that "bismuth was retained and stored in the different tissues to the extent of about 50 per cent. over a period of six months." I have never been able to confirm these findings; on the contrary, I found in experiments with guinea-pigs that after ten days only 5 to 12 per cent. of the injected quantity was stored in this way. Details were given in a recent publication (*Arch. Derm. and Syph.*, June, 1929).

The therapeutical results of this watery suspension of bismuth, which was prepared after my instructions by a Danish firm under the name of "Ido-Bi," were in all respects satisfactory. It was always combined with treatment by neosalvarsan (Höchst). This makes it difficult to state the role played respectively by the bismuth and by the salvarsan. It may be of some interest to study the clinical result of this treatment by neosalvarsan combined with watery suspension of bismuth, first of hydroxide, later, and chiefly, of oxychloride.

In the period July 1st, 1924, to January 1st, 1928, 161 cases of syphilis, not treated before, were put under treatment. Of these, 9 discontinued treatment before a serological control of the effect was made. Of the remaining 152, 96 were men—29 in the primary sero-negative stage, 36 in the primary sero-positive stage, and 31 in the so-called secondary stage. No men were seen with old, unrecognized neglected syphilis. This is now very rarely met with in men in Copenhagen, owing to the ample access to free treatment provided by the municipality. Practically all men with venereal diseases go now to a specialist as soon as the first sign is observed. It is slightly different with the women. Out of the 56 women with unrecognized syphilis 5 were in the primary stage, 4 were suffering from latent syphilis, which was not recognized until the birth of a child with congenital syphilis, 3 had tertiary signs, the remaining 44 were suffering from recent secondary syphilis.

The treatment given was: injections of neosalvarsan, generally in doses of 75 cg. to men and 60 cg. to women. Persons of smaller size were given: 60 cg. to men and 45 cg. to women. The series used to be of four to six injections with an interval of a week. The routine scheme was a treatment of two years with three series of six injections of neosalvarsan, and with six series of ten injections of bismuth oxychloride. This amount was only obtained with the minor part. The average amount given to the 152 patients here considered was ten injections of neosalvarsan and thirty-five injections of bismuth. Also it must be emphasized that the treatment was by no means given in a definite routine way. Light cases were discharged with less treatment, resistant ones (with resistant gland swellings, resistant serum reactions, etc.) considerably more. The clinical result can be given quite shortly: No clinical relapse was seen; nine pregnant women all bore healthy children. At the last serological examination 143 out of the 152 patients gave a perfectly negative Wassermann reaction; two women gave a feebly positive test (one suffering from a latent unrecognized syphilis, the other from a neglected severe secondary eruption). Four men and three women showed a ± reaction of the Wassermann test. It seems justifiable to characterize these results as satisfactory. It is impossible to decide how much of the result is due to the salvarsan and how much to the bismuth treatment. However, it can be said that the scheme used has proved to be effective.

Summary.

1. Bismuth as a substitute is superior to mercury.

2. Internal and percutaneous administration is ineffective owing to restricted and irregular absorption of bismuth.

3. Intravenous treatment is dangerous in large doses; not sufficiently effective in well-tolerated doses; impracticable, as it requires frequent injections.

4. Intramuscular treatment remains the treatment to be preferred. Its aim is to secure a fairly quick, regular, effective saturation of the body, without risk of intoxication. As to the different forms of treatment the following outlines may be given: (*a*) Watery solutions are effective, but somewhat painful and troublesome because they require frequent injection. (*b*) Oily solutions are almost painless, but not especially rapidly absorbed. Their therapeutical power is reported by many to be good. (*c*) Oily suspensions are generally painless, but their absorption is somewhat slow and therefore often rather irregular. Preference should be given to the compounds that are not quite insoluble in water. Bismuth salicylate seems to be one of the best.

5. Watery suspensions are absorbed rather quickly and are therefore slightly painful. Preference should be given to compounds of restricted solubility. The oxychloride possesses the qualities of absolute purity and stability. With particles of a size of 3 to 5 μ it is almost painless and very powerful. I think this preparation especially good on account of its reliability and effectiveness.

6. The daily dose of bismuth metal may be fixed at about 0.5 mg. per kilo of body weight. Higher doses are required with remedies of a slow and incomplete absorption.

7. I recommend as a routine measure the administration of neosalvarsan in doses of 60 to 70 cg. given in series of five to six intravenous injections, and of bismuth oxychloride in watery suspension in doses of 15 to 20 cg. and in series of eight to ten intramuscular injections; to a total number of about 18 neosalvarsan injections and 60 bismuth oxychloride injections in a period of about two years. Even in an incomplete form this scheme proved definitely effective. Of 152 patients with fresh syphilis no clinical relapse was seen during and after the treatment. None of the women treated gave birth to a child with congenital syphilis. By the end of the treatment 2 patients only showed a positive Wassermann reaction, 7 a doubtful, 143 a definitely negative test.

8. No treatment of syphilis should be given as a mere routine, but each single case must be considered by itself and treated accordingly.

9. Retention of bismuth in the organism depends on two different factors. Diffuse storage in the different organs of the body is a matter of slight significance; it amounts to scarcely more than 100–150 mg. after an intensive course.[9] The unabsorbed deposits, however, may contain unlimited quantities of bismuth, especially in the case of compounds that are absorbed slowly. This second factor is an important but rather capricious and slightly dangerous item in intermittent syphilis treatment.

10. To avoid an intravascular injection taking the place of an intramuscular it is recommended not only to make an aspiration but also to retract the needle slightly during the injection.

ETHYLENE ANAESTHESIA.*

BY

H. P. FAIRLIE, M.D.,

ANAESTHETIST, GLASGOW WESTERN INFIRMARY, AND THE ROYAL HOSPITAL FOR SICK CHILDREN.

ETHYLENE gas is administered as an anaesthetic along with oxygen, the proportions of the two gases in the mixture being to some extent variable. Usually the most suitable mixture contains about 88 per cent. of ethylene, 12 per cent. of oxygen; but anything from 10 up to 25 per cent. of oxygen may be found necessary. This variability depends on a number of factors—for example, the age and build of the patient, the condition of the heart and lungs, the nature of the operation, etc. In all administrations the oxygen percentage must be maintained at such a level as will prevent respiratory failure. More than a slight degree of cyanosis is not allowable, and should be regarded as a warning of impending danger. With due regard to this the anaesthesia is a safe one, trouble arising primarily from failure of respiration and corresponding to "blue collapse"—not the "white collapse" which originates from sudden heart failure. The corrective for "blue collapse" with ethylene is the same as with other anaesthetics—namely, an increase in the proportion of oxygen up to 50, 75, or even 100 per cent. until cyanosis disappears.

I always employ rebreathing. The administration, therefore, closely resembles that of nitrous oxide and oxygen, and the same apparatus serves very well for both gases. The principal difference lies in the slightly higher percentage of oxygen when ethylene is the anaesthetic, and the resulting absence of, or lesser degree of, cyanosis.

The question very naturally arises, Do we gain anything by using ethylene which nitrous oxide cannot give us? I think that in Great Britain, judging from the scanty references to ethylene, this has been answered for the most part in the negative, and there are undoubtedly grounds for this attitude. At the same time I feel that my answer to the question would be affirmative and that ethylene is finding a definite place among the anaesthetics which I regularly employ. In many respects the results obtained closely resemble those obtained by nitrous oxide and oxygen—for example, safety, rapid action, rapid excretion, and relative immunity from unpleasant after-effects.

There are two decided points of difference between the two gases, one favourable, the other unfavourable, to ethylene. The first difference is the more profound type of anaesthesia which ethylene develops. I have repeatedly had this clearly demonstrated. An anaesthesia which just failed to achieve the desired depth with nitrous oxide-oxygen would become quite satisfactory with ethylene-oxygen. True, in such cases the alternative is offered of supplementing nitrous oxide with ether, but the immunity from unpleasant sequels is then to a greater extent limited. In all cases where I expect a considerable demand as regards depth of anaesthesia I prefer to commence with ethylene. Even then if ether has to be added a smaller quantity suffices than if nitrous oxide had been used. Herein, then, lies the chief superiority of ethylene over nitrous oxide—the more profound narcosis which it produces. It is thereby rendered sufficient for a wider range of operations. It is quite adequate alone for some laparotomies, and for more with the minimum admixture of ether. The second difference, and the one in which ethylene compares unfavourably, rests on one of its physical properties. Ethylene gas, as ordinarily obtainable, possesses a very unpleasant odour. Fortunately, this property is practically without effect on the patient, but for the other inhabitants of the operating theatre it presents a serious objection. I can only suggest in mitigation the flavouring of the gas with oil of eucalyptus, which renders it more bearable.

In order to review the scope and usefulness of ethylene in a general way, I propose to regard it from three viewpoints: (1) the patient's; (2) the surgeon's; (3) the anaesthetist's.

The Patient's Point of View.

The patient's chief interest in his anaesthetic is centred in his experiences "going under" and "coming out." I ought to remark here that I rarely employ ethylene without a preliminary dose of morphine and hyoscine. The reaction to the taking of the anaesthetic is therefore modified by this preliminary narcotic. I regard the addition of hyoscine as valuable not only in allaying nervousness and inducing a drowsy condition favourable to the induction of anaesthesia, but also for its action on the memory. Many patients, especially the elderly, after a dose of hyoscine, have only hazy recollections, or none at all, of being moved from bed to the theatre. Very often there is a more or less complete blank lasting some little time after their return to bed. But even in the absence of preliminary medication the taking of ethylene does not give rise to the disagreeable sensations which one would expect. I have repeatedly questioned patients about their sensations, and not one has made any reference to the peculiar smell. By taking the gas in full, or nearly full, strength the smell appears to be unnoticed. Consciousness is rapidly abolished, and usually without evidence of resentment or excitement. As regards the "coming out" stage, again the sensations appear to be not unpleasant. Vomiting occurs fairly frequently (in about 75 per cent.), but as a rule within a minute or two of the end of the administration and before consciousness has returned. Thereafter there is seldom any more, though

* Read in the Section of Anaesthetics at the Annual Meeting of the British Medical Association, Manchester, 1929.

in occasional cases nausea and vomiting persist for a time, even up to twenty-four hours. There is no unpleasant taste or smell lingering.

On questioning a medical man to whom I recently administered ethylene for an appendix operation and colopexy his criticism was that "the experience was not at all unpleasant either going under or coming out."

The Surgeon's Point of View.

From the surgeon's viewpoint several factors come into play, depending largely on the type of operation. The principal criticisms are directed towards insufficient relaxation and haemorrhage. In operations where neither of these is of serious moment the anaesthesia meets most requirements.

The Anaesthetist's Point of View.

Lastly, the anaesthetist, though dealing with an anaesthetic which requires an elaborate apparatus, and an anaesthesia demanding experience and constant watchfulness to maintain within its rather narrow margins, is working within fairly wide limits of safety. In the asphyxial stage, which develops when too little oxygen is allowed respiratory failure definitely precedes cardiac failure. Ample warning is therefore given by the dark colour of the blood. If this be observed early, and dealt with immediately by an adequate increase in the oxygen content, it is rare that any further steps are necessary. In an experience extending to over a thousand administrations I have only seen six instances of serious respiratory collapse with cessation of breathing. In four of these by administering pure oxygen under positive pressure, very easily carried out with McKesson's apparatus, a return of breathing was quickly obtained. In the other two cases this had to be supplemented for brief periods by rhythmic chest compression.

There is one other physical property of ethylene besides its odour to which reference must be made. It is very inflammable, and in mixtures with air or oxygen may readily be ignited and even exploded. In the United States cases of explosion have been recorded. So far as I am aware none has happened in this country. The nature of the hospital buildings and the drier atmosphere of the States probably combine to promote conditions more favourable to this occurrence. I think that, in this country, it is sufficient to remember that ethylene must not be administered in any room where there is an open fire or naked light, nor in any case where cautery or diathermy is to be used.

I have attempted briefly to outline the scope and limitations of ethylene as an anaesthetic. To those who are familiar with nitrous oxide and oxygen it presents no difficulties, and is well worth a trial. I personally should now regret not having it available for many cases in which I think it is the best anaesthetic.

ERYTHRAEMIA WITH A HIGH DEGREE OF ACHOLURIC JAUNDICE:

PROBABLY A MANIFESTATION OF COMPENSATORY "HYPERSPLENISM."

BY

F. PARKES WEBER, M.D., F.R.C.P.,

SENIOR PHYSICIAN TO THE GERMAN HOSPITAL, LONDON.

SOME excess of urobilin in the urine has not rarely been observed in patients suffering from erythraemia (splenomegalic polycythaemia). Lommel, and Löw and Popper, found the total excretion of urobilin and urobilinogen above the average, and the blood bilirubin may be in excess, but it is very rarely sufficiently so to give rise to actual (acholuric) jaundice. I have never myself seen or heard of the occurrence in England of another case of jaundiced erythraemia* like that of the present patient, whom I first saw in April, 1929, by the kindness of Dr. S. S. Chesser. She then showed, as she still (October 17th, 1929) does, considerable jaundice, without bilirubin in the urine (acholuric jaundice), but with a very highly positive *indirect* Hijmans van den Bergh reaction in the blood plasma—that is to say, for "blood bilirubin" (which, by the by, I believe to be the same as Virchow's "haematoidin").

The patient,† a Welsh woman, married, aged 40 years, living near London, has a typical "erythraemic" appearance and is markedly jaundiced (examined in April and May and October, 1929). Height 152.4 cm.; weight 71.6 kilograms in May, and about 1½ kilograms more in October, 1929. There is decided excess of subcutaneous fat over the thighs, buttocks, and abdomen. Examination of the thorax shows nothing special, excepting (by *x* rays) rather excessive bronchial markings and very slight enlargement of the aortic arch.

The spleen is enlarged and feels rather firm, the lower edge reaching three fingerbreadths below the costal margin. The liver (not abnormally hard) can be palpated three and a half fingerbreadths below the ribs in the right nipple line. No ascites. No subcutaneous oedema. Menstruation regular. Bowels not confined. Brachial blood pressure 165/95 mm. Hg. Urine (October 17th): specific gravity 1011; clear; rather high yellow; acid; a little albumin (moderate "cloud" on boiling); no sugar; excess of urobilin and urobilinogen; no bilirubin; excess of indican; one or two hyaline tube casts seen in the centrifuge sediment. Ophthalmoscopic examination shows a typically "erythraemic fundus." Basal metabolism (two estimations), 127 per cent.

Blood count (April 29th): haemoglobin 120 per cent.; erythrocytes, 7,880,000 per c.mm. of blood; colour index = 0.76; white cells 16,350 (polymorphonuclears 70 per cent., basophils 3 per cent., eosinophils 3 per cent., lymphocytes 21 per cent., monocytes 3 per cent.); no nucleated or abnormal red cells seen. Thrombocytes: 1,512,960 per c.mm. of blood. The blood serum gives an extremely strong positive indirect Hijmans van den Bergh reaction for "blood bilirubin." The resistance of the washed erythrocytes towards graduated hypotonic sodium chloride solutions seems to be within normal limits, haemolysis commencing with the 0.5 per cent. solution and becoming complete with the 0.32 per cent. solution. The blood serum gives negative Wassermann and Meinicke reactions. Dr. T. C. Hunt kindly estimated the cholesterol in the blood serum by the Autenrieth colorimetric method (as described by L. Pincussen, *Mikromethodik*, fourth edition, Leipzig, 1928, p. 143), and found it to be 190 mg. per 100 c.cm. A recent blood count (October 17th) showed decided increase in the polycythaemia: haemoglobin 125 per cent.; erythrocytes 8,900,000; colour index = 0.7; white cells 18,650. The erythrocyte count still more recently (November 7th) was 10,100,000.

The patient was married at 21 years of age and has had three children (all living and healthy); no miscarriages. There is nothing special in her family history. She is said to have had typhoid fever in childhood. Her first attack of jaundice was eight or nine years ago, and since then she has had many icteric exacerbations, but of late seems never to have become quite free from jaundice. She began to suffer from vertigo twelve years ago, and the giddiness is worse during the exacerbations of jaundice. The attacks of giddiness come on especially when she is walking in the open air, and during a recent attack she fell and cut her forehead (October 15th). For a long time she has been subject to occasional attacks of pain in the left lumbar region, passing down the outer part of the left thigh, but she has had no attack suggesting biliary colic. She suffers from occasional epistaxis and often has severe headaches. It was five years ago that she first noticed that her face had become redder and that she flushed very easily. She has been relieved by blood-letting, and this is to be carried out again. It is certain that her jaundice varies much in degree. In fact, at times there is no obvious jaundice.

Remarks.

It seems probable that the chronic acholuric jaundice and the icteric exacerbations in the present case are due to active destruction of the erythrocytes in the spleen (and possibly in other parts of the reticulo-endothelial system), but there is no evidence of abnormal "fragility" of the red cells. The jaundice might therefore be interpreted as the manifestation of a spontaneous attempt to compensate for the excessive production of erythrocytes in the bone marrow by increased haemolysis in the spleen—a compensatory form of "hypersplenism."* Periodic blood-letting would seem to be the safest treatment in such a

* For references to the literature on the association of erythraemia with jaundice and also with hepatic cirrhosis see Weber and Bode, *Polycythaemia, etc.*, London, 1929, p. 13.

† The case was demonstrated, but not exactly described, at the meeting of the Clinical Section of the Royal Society of Medicine on November 8th, 1929.

* If this is so an increase in the degree of jaundice should be accompanied by a decrease in the erythrocyte count. On one occasion we have noted a decrease in her jaundice accompanied by an increase in her erythrocyte count.

case; phenyl-hydrazine is perhaps contraindicated, since, by further destruction of erythrocytes, it might not only increase the jaundice but also favour the tendency to formation of bilirubin calculi, and possibly even produce hepatic cirrhosis.

My explanation of the whole morbid syndrome in the present case is therefore as follows. The primary "agent"* is the erythraemia, which is an "idiopathic" increase of the total erythrocytes and erythroblastic bone marrow in the body—that is to say, an idiopathic increase of the "erythron," the term proposed by Professor A. E. Boycott in his recent presidential address before the Section of Pathology of the Royal Society of Medicine. If we regard the "erythron" as a tissue-organ or tissue-system (as we regard the reticulo-endothelial system and the total lymph-adenoid tissue of the body), the increase in question must be of the nature of a primary diffuse but non-malignant neoplasm (a "neoplastic diffuse overgrowth"), and not of the nature of a secondary compensatory hypertrophy, such as we get in the polycythaemia of high altitudes, the polycythaemia of congenital heart diseases, and the polycythaemia connected with circulatory obstruction in the lungs—for example, in "Ayerza's disease." A true *neoplastic* overgrowth of the "erythron" is useless and harmful to the rest of the body, and in the present case a spontaneous compensatory *reaction* on the part of the spleen has taken place—namely, an increase of one of the splenic functions (a compensatory "hypersplenism"), with the object of destroying the superfluous erythrocytes. This in its turn gives rise to excess of the blood bilirubin and to a condition of acholuric jaundice, but is nevertheless insufficient to prevent the gradual further increase of the "erythron," which will have to be met by blood-letting. It is just possible that a diet qualitatively the reverse of that employed for pernicious anaemia may likewise be of some use.

SECONDARY COMPLICATIONS IN PATIENTS SUFFERING FROM EMPYEMA OF THE PLEURA.

BY

L. HOFBAUER, M.D.,

CHIEF OF THE DEPARTMENT FOR RESPIRATORY DISEASES, FIRST MEDICAL CLINIC, VIENNA.

By an operation for empyema dangers which threaten life are avoided, but the *restitutio ad integrum* is seldom attained. On the contrary, prolonged suppuration often follows (with, sometimes, death due to exhaustion), and repeated operations may be required. At the least, disability, disfigurement, and marked pathological conditions ensue. The surgeon's life-saving intervention may be criticized by the patient's relatives, and therefore fall into discredit. Taking the view that the untoward consequences are due to the wide opening of the chest, Lister adopted a method of treatment which avoided this, while Wenckebach prefers the thoracic puncture, followed by substitution of the exudate by air. Many excellent results have been obtained by this method, especially in cases of tuberculous empyema; but not all cases of empyema can be treated in this manner. Hathaway has shown that coagulated fibrin in the form of blood clot is an excellent culture medium for pyogenic bacteria. The clot, therefore, must first be removed, and this is only possible with a widely opened pleural cavity.

Post-operative complications are to be found, however, whether the chest is widely opened or not. They may be classified in the following groups: (1) deformities, especially of the thorax; (2) functional troubles, including dyspnoea and disturbances of the circulation; (3) dangers to life, such as arise from the "pyothorax *ex vacuo*."

Massive adhesions, the result of insufficient resorption of the exudate, are generally believed to be the cause of the first group. Attempts were made, therefore, to empty the effusion as thoroughly as possible; often, however, there are insurmountable difficulties to doing this completely, and even when all the effusion has been removed the patients suffer from the complaints already mentioned, sometimes in the highest degree. Those cases in which complete elimination of the exudate is attained by the Monzingo form of drainage show the greatest changes. Severe symptoms of breathlessness, oppression, and a peculiar type of dyspnoea are present, although the *x*-ray examination shows that the pleural space is entirely free from exudate.

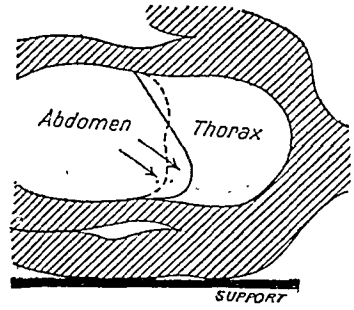

FIG. 1.—Dislocation of the diaphragm by bending. ——— Position of the organ in a bending man. - - - - - Position of the organ in a sitting man.

As soon as these patients try to bend sideways they experience a feeling of constriction in the chest, with pain and the sensation that they cannot get enough air. In many patients this symptom appears only when bending over to the diseased side; in others, when they bend to the sound side.

These complaints are comprehensible when it is remembered that they correlate with the presence of adhesions of the diaphragm to the bony wall and disappearance of the phrenico-costal angle. The condition becomes obvious when comparison is made with the normal displacement of the diaphragm following the bending of the body sideways. The lower part of the diaphragm is displaced upwards into the thoracic cavity, while the upper half descends into the abdominal cavity. The reason for this dislocation is that the intestines fall on the lower half of the diaphragm (Fig. 1); the abdominal pressure on this area becomes increased, therefore, and the upper part of the diaphragm is pulled downwards. The phrenico-costal angle opens on this latter side to its fullest extent.

The presence of scar tissue in the phrenico-costal angle interferes with its opening. The patient feels pain when

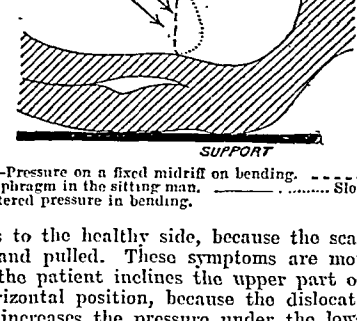

FIG. 2.—Pressure on a fixed midriff on bending. - - - - - Position of the diaphragm in the sitting man. ——— . ..... Slope caused by the altered pressure in bending.

he inclines to the healthy side, because the scar tissue is stretched and pulled. These symptoms are more marked the more the patient inclines the upper part of his body to the horizontal position, because the dislocation of the intestines increases the pressure under the lower part of the diaphragm the more the body is bent. On the other hand, when fixed to the thoracic wall the diaphragm cannot follow the increased abdominal pressure when the patient bends his body to the diseased side; it becomes expanded (Fig. 2), and the patient feels pain owing to stretching of the adhesions and involvement of the nerves.

*I use the term (morbid) "agent" as something which provokes a compensatory or conservative "reaction" (compare my short paper, "A Note on Action and Reaction in Pathology and Therapeutics," *St. Bartholomew's Hospital Reports*, London, 1903, xxxix, p. 139).

These effects make the sick person avoid every bending of the body to the side, and especially the lateral sleeping position. This symptom of "clinophoby" (from κλίνειν, to bend, and φοβεῖν, to fear) is not always developed in the same manner; it occurs in some patients when bending to the side, in others, while bending forwards or backwards. It is often absent in the beginning of the movement. The patient can lie for a short time on the side and even fall asleep in this position, but soon awakes with a feeling of pain or breathlessness, which compels him to sit erect or to turn while sleeping to the other side or the back.

The scars in the phrenico-costal angle are often not to be seen when only an x-ray plate is made. In such cases it is absolutely necessary to record the respiratory movements of the diaphragm on the x-ray screen, and to compare the inspiratory and expiratory forms of the diaphragm vault. The scar tissue produces a malformation of the diaphragm or a disappearance of the phrenico-costal angle. The systematic examination of these patients shows that a constant relation is to be found between the form of clinophoby and the seat of the adhesion; if pain arises when the patient inclines to the side, an adhesion is found at the side; if bending forwards or backwards produces the pain, the adhesion is either in the anterior or posterior part of the phrenico-costal slit. Further evidence of the truth of the statement that the adhesions cause the clinophoby is given by the results of the respiratory treatment of these complaints. First it must be noted that, not only is the position of the diaphragm altered by bending, but also the function: the respiratory movements of the organ are changed very distinctly thereby. The excursions of the two halves are not varied in the same manner (Fig. 3); the lower half is now moved much more extensively than in the standing position, while the upper half shows hardly any respiratory movements. This astonishing functional manifestation takes place in the examination of every healthy person.

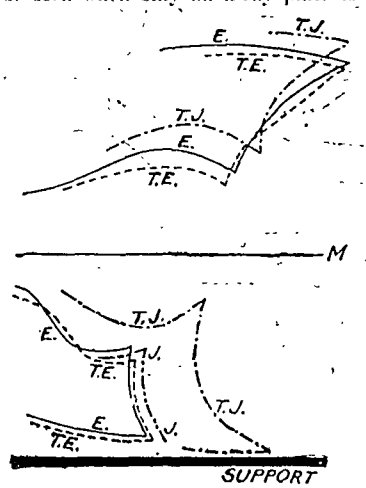

FIG. 3.—Movements of the diaphragm in a bending man. The lower part executes great movements; the upper half very little at all. ——.——.——J. = Inspiration. ———E.= Expiration. —.—.—. T.J.= Deep inspiration. - - - - - T.E.= Deep expiration. M.= Midline.

After a puncture or an operation a portion of the exudate accumulates, mostly at the base of the pleural cavity. The diaphragm is pushed downwards, not only by the weight of the effusion, but by the diminution of the intrathoracic suction due to the resulting negative pressure. Fixation of the inspiratory position of the diaphragm results, and no movement can take place in consequence of the inspiratory contraction of its muscle fibres. This functional elimination of the respiratory movements brings about persistence of the effusion in the basal portions of the pleural cavity. Some time ago Grober was able to show by means of experimental studies that the respiratory movements of the chest wall are the most important factor, as regards absorption in the pleural space, not only of fluid but also of solid corpuscular elements. It can therefore be easily understood why an accumulation of scars in nearly all cases of pleurisy can be found at the end of treatment, especially in the basal parts. Also in our own cases marked remnants of the effusion were present in the supradiaphragmatic part of the pleural cavity.

The question arises whether it is possible to diminish the effusion by increasing the respiratory movements, especially of the diaphragm. In order to stimulate the visible movements of the diaphragm it is necessary first to improve its position before the beginning of the inspiratory action of its muscle fibres. It must approach the normal expiratory elevation in the thoracic cavity. This elevation can be augmented by bending the body to the side (Fig. 1). The patients are told to lie down on the affected side several times a day for some length of time. In the beginning the pain necessitates a variation of this treatment. When the body is held vertically, leaning against a vertical support, the upper part of the body can make a rotation to the side without breathlessness or pain being felt. In this position the intestines barely press on the lower surface of the diaphragm, because they do not come directly in contact with it, but only with the side walls of the abdominal cavity. After a time the physician tries a slight bending of the body backwards before beginning this static exercise of bending sideways. The body is approached to the horizontal position until the patient, turning afterwards to the side, feels only a little unpleasantness. Stronger traction on the scar tissue, and especially any risk of rupturing it, must be avoided absolutely. At first the patient remains in this position only a few minutes, but later the period is increased. He soon feels quite at ease in this position, and can continue to rest comfortably in it for a long time. Then the vertical standing support is brought a little nearer to the horizontal position; the back of the patient is therefore approximated to the horizontal, and the rotation of the body to the side is repeated. By means of this treatment in all cases it was possible slowly to enable the patients to lie permanently on both sides without pain or discomfort, and to sleep on the side through the entire night.

These exercises hasten the gradual return of the diaphragm to the normal position; the force of its muscle fibres also assists the respiratory movements. X-ray examinations during treatment reveal a definite increase in the respiratory excursion, an effect which becomes greater when the physiologically active expiratory forces, the abdominal muscles, assist in strengthening this action. This may be obtained by certain respiratory exercises, especially by humming exercises. In this way the attention of the sick person is concentrated on the expirations because they are controlled by the ear; he learns to lengthen and strengthen the expiratory action, and also to avoid the perilous "pressing expiration." At the end of the humming the abdomen sinks in more and more, and the abdominal wall becomes firm from the progressive exercising of its muscles. The following inspiration allows the abdomen to return to its primitive form with relaxed walls; this takes place passively, the muscular contraction ceasing. At the end of the exercise the abdomen is pushed forward actively, the diaphragmatic muscle fibres contract during the inspiration, and push the intestines downwards; thereby the abdominal walls are compelled to go forwards. In this way the respiratory action of the diaphragm shows a gradual improvement.

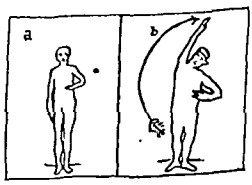

FIG. 4.—Humming exercise combined with arm movement. *a* = In the beginning of the inspiration. *b* = After a full inspiration.

The same process is necessary for the bony parts of the thorax. Strong masses of scar tissue are often to be found, and there are always adhesions which are attached to the ribs and hinder their respiratory movements. The return to normal is accomplished in the following manner. The patient learns a combination of the humming exercise with arm movements; the hand of the healthy side embraces the chest during inspiration to avoid, by pressure against it, any increase in the "vicarious emphysema" on the sound side; the diseased side is thus compelled to make greater respiratory movements. The arm of this same side is stretched and lifted up to the vertical position (Fig. 4*b*) to strengthen the action of the inspiratory muscles. During the humming expiration the arm descends until it touches the hip (Fig. 4*a*). In the beginning too energetic action

must be avoided, especially if pain is produced. The full development of these respiratory exercises proceeds very slowly; the complete treatment considerably influences the adhesions and scars in the pleural space, the effusion and its consequences often disappearing entirely (Figs. 5 and 6).

Special attention was given to the secondary deformities produced in the trunk, inasmuch as very different alterations may develop after pleural effusions. There may be a lower or higher position of the shoulder on the diseased side (Fig. 7); a scoliosis, curving either to the sound or to the affected side, may originate in consequence of an empyema. The pathogenesis of these morbid changes is difficult to determine, and "post-empyema scoliosis," though it has been studied for a long time, is not yet definitely understood. In the majority of the cases the convexity of the vertebral column bends to the healthy side, but in the minority the reverse is to be seen, the concavity being turned to the sound side. The systematic study of our own cases shows a constant relationship between the behaviour of the diaphragm and the vertebral column; malformation of the diaphragm was always accompanied with a convexity of the spine towards the healthy side, combined with a descent of the shoulder on the diseased side. When the diaphragm moved freely, or when a thick mass filled the widely opened phrenico-costal angle, the concavity of the vertebral column was seen towards the healthy side, associated with an ascent of the shoulder on the affected side. These deformities were definitely benefited by the previously mentioned exercises. Depending on the reactivation of the diaphragmatic respiratory action the crookedness of the trunk proportionally disappears.

All our observations support an explanation of the pathogenesis of these deformities on the following lines. A *defense musculaire* is originated by the inflammatory irritation of the pleura—that is, by the pains resulting from the respiratory movements. If only the upper parts are irritated the back muscles are contracted; ascent of the shoulder and convexity of the vertebral column on the affected side develop in consequence of this, but the latter only if the contracture is stronger and the pain due to respiration is longer lasting. These consequences are only possible in such cases where the irritation of the upper parts is not accompanied with involvement of the pleura in the phrenico-costal angle; for if there is a fixation of the diaphragm on the ribs the contracture of the back muscles causes pain, because the elevation of the thoracic wall produces an opening of the split between the diaphragm and the costal pleura. The patient will therefore avoid every action of these muscles, the tonus becomes diminished, and a dropping of the shoulder appears, which is often associated with a curvature of the vertebral column. The concavity to the affected side must occur, because the tonus of the back muscles is there diminished.

FIG. 5.—The pathological state following a right empyema two years after the surgical treatment.

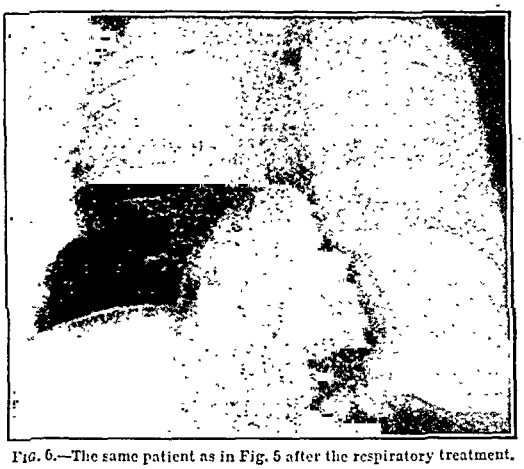

FIG. 6.—The same patient as in Fig. 5 after the respiratory treatment.

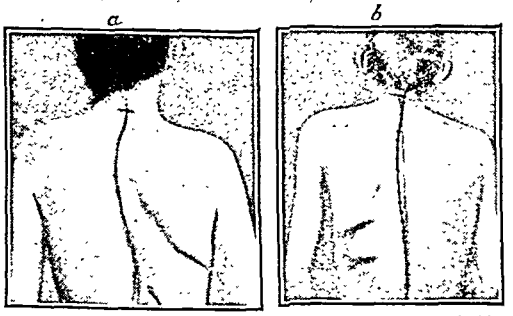

FIG. 7.—Post-empyema scoliosis.
b = Curved to the affected side.
a = Curved to the sound side.

Besides these secondary troubles there are to be found more serious complications in some cases, and especially long-lasting suppuration, the "pyothorax *ex vacuo*," which often leads to death from amyloid disease, even though the patient may be operated upon several times. It is suggested that the suppuration is only the consequence of the existence of free air spaces between the visceral and parietal pleura; plastic operations are performed, therefore, to bring the two serous membranes together. The results of animal experiments and of clinical experience show that the filling of the lungs with air depends on their respiratory action; it is diminished in the lobes adjoining the effusion, but later increases with respiratory activation (Figs. 5 and 6). The retraction of the pulmonary tissue from the thoracic wall is effected by the diminished respiratory function; it can be paralysed in some cases by respiratory reactivation. Although excellent results were frequently obtained, failures were seen in some cases. The cause of the delay in recovery in such cases must be sought and can nearly always be found. In the majority of cases the suppuration is caused by foreign bodies resting in the pleural cavity, especially pieces of rubber broken off from a drainage tube or a clot of fibrin, these being breeding places for the pyogenic bacteria.

Conclusion.

All the secondary morbid manifestations after empyema are caused by disturbances of the respiratory function. They can be divided into subjective symptoms, such as dyspnoea, and into organic crippling malformation of the trunk. Proof of the correctness of this view is afforded by their successful treatment with systematic breathing exercises, which bring about their complete disappearance.

THE SIGNIFICANCE OF CHOLESTEROL IN PHYSIOLOGY AND PATHOLOGY:

*A CONSIDERATION OF SELECTED PROBLEMS.**

BY

E. NOBLE CHAMBERLAIN, M.D., M.Sc., M.R.C.P.,

HONORARY ASSISTANT PHYSICIAN, ROYAL SOUTHERN HOSPITAL, LIVERPOOL; LECTURER ON PHYSIOLOGY AND DEMONSTRATOR IN MEDICINE, UNIVERSITY OF LIVERPOOL.

In this abstract it will not be possible to deal with the physiological aspects of this subject, but certain points must be mentioned briefly in view of their direct bearing on the pathological problems to be considered later.

Cholesterol is excreted from the body through the media of the bile, intestinal mucosa, and skin. The last of these appears to have been neglected in the literature, but since cholesterol is contained in appreciable amounts in the superficial layers of the skin, the desquamation of this will lead to its loss. The lost cholesterol is replenished mainly from food, but at certain times it is probable that a supplementary supply is derived from synthesis. The most likely site for such synthesis is the suprarenal glands. This view was put forward by the French school some years ago, and, though denied by the German school, has received fresh support from personal observations by myself.[1]

In spite of the somewhat coarse mechanism of intake and output of cholesterol, the blood cholesterol in an individual remains remarkably constant, suggesting that some finer mechanism is at work. I have shown that the spleen possesses the property of removing excessive amounts of cholesterol from the blood; this, in conjunction with the observations of other writers, suggests the possibility that the spleen may have a function as a regulator of blood cholesterol.

The relations of cholesterol to certain important pathological problems may now be considered, but it must be mentioned that in this abstract it has not been possible to give a complete account of the relationship of cholesterol to pathology, and greater attention has been paid to those problems in which the cholesterol changes are beyond doubt, than to those where such changes are still disputed. The object has been to select certain of the more important pathological problems and discuss their relations with cholesterol, and particularly to endeavour in each case to explain the pathological findings from a physiological standpoint.

Before describing these conditions, it must be mentioned that whenever reference is made to "blood cholesterol" the figures refer to estimations made either on the whole blood or on the plasma, unless it is otherwise stated. The amount in each is approximately the same, but in disease variations are most commonly found in the plasma, and most observations have been made on this part of the blood. Estimations on whole blood, however, also give fairly reliable information, as the amount of cholesterol in the corpuscles remains practically constant. Again, unless specially mentioned, the figures refer to total cholesterol—that is to say, to both free and ester cholesterol.

Cholesterol in Nephritis.

The first disease to be described here, in which notable changes in cholesterol metabolism have been found, is nephritis. The earlier investigations by Klinkert,[2] Grigaut, Laroche, Chauffard,[3] and Epstein,[4] showed that blood cholesterol was frequently raised in this condition, but their observations were comparatively few, and little attempt was made to determine whether or not this rise occurred in all forms of nephritis. A recent paper by Maxwell,[5] however, deals with a large number of cases investigated from this point of view, and many valuable observations have been recorded, some of which have been confirmed by my personal investigations.

The most marked changes in cholesterol metabolism are found in the so-called chronic parenchymatous variety of nephritis, a disease characterized by oedema, marked albuminuria, and anaemia. Cardio-vascular changes are often present, but do not form a prominent feature of the clinical picture. In this type of disease the blood cholesterol is frequently raised from a normal of 140 to 180 mg. per cent. to figures between 400 and 600 mg. per cent. or more. Usually the rise of cholesterol is more or less proportionate to the degree of oedema present, so that it has been suggested by some authorities that hypercholesterinaemia and oedema are related as cause and effect. As Maxwell points out, however, there are numerous cases in which the degree of oedema and the blood cholesterol do not run parallel, and, in fact, cases are found with a high blood cholesterol and no oedema, so that it is more likely that there is some common cause responsible both for the oedema and the hypercholesterinaemia. With improvement in the clinical condition there is as a rule a fall in the blood cholesterol, often running parallel with the disappearance of the oedema. In certain cases, however, the blood cholesterol remains high after all oedema has gone, and these cases usually have an unfavourable outlook, and the degree of hypercholesterinaemia, therefore, is a sign of some *prognostic importance*.

In acute nephritis, generally recognized by some degree of oedema, of haematuria and albuminuria, and by its comparatively sudden onset, a similar state of affairs prevails as in chronic parenchymatous nephritis. The blood cholesterol is considerably raised, perhaps to 200 or 300 mg. per cent., but rarely reaches the very high figures sometimes seen in the chronic parenchymatous variety. Its level is also roughly proportionate to the degree of oedema. In cases which subside completely, as do a considerable number of cases of acute nephritis, particularly in children, the blood cholesterol decreases with the clinical improvement, but Maxwell finds that in those cases which progress to chronic parenchymatous nephritis the cholesterol remains high. Here again, therefore, the blood cholesterol may form some index of the progress and ultimate end of the disease.

The type of disease which is commonly called interstitial nephritis is a somewhat ill-defined condition, closely associated with arterio-sclerosis and high blood pressure, and difficult to separate from these conditions. Thus it is not surprising that authorities do not agree on the cholesterol findings. If we accept as a definition of chronic interstitial nephritis a disease characterized by the presence of polyuria, especially nocturnal, by slight albuminuria and nitrogen retention in the blood, estimations of blood cholesterol in such a disease usually reveal no significant changes. If, however, the dominant feature of the disease is arterio-sclerosis, the cholesterol is usually increased to some extent, the figures reaching 200 to 260 mg. per cent.

It is interesting to note here that whilst acute nephritis and the chronic parenchymatous form are associated with considerable oedema and a marked rise of blood cholesterol, the chronic interstitial form, with its small rise of blood cholesterol, is rarely accompanied by much oedema, unless in the terminal phases of the disease as an expression of cardiac failure. This suggests that the two types of the disease are essentially different in their nature, as indeed their causation and general course would lead one to expect.

Epstein[6] regards chronic parenchymatous nephritis as a metabolic disorder associated in most cases with hypothyroidism. He points out that in both these conditions there is a lowered basal metabolic rate, accompanied by changes in the subcutaneous tissues. Supporting this argument he observes that in hypothyroidism, as in parenchymatous nephritis, there is a rise of blood cholesterol, which, he says, is inversely proportionate to the metabolic rate.

Gardner and Gainsborough,[7] in some recent investigations on this problem, although they confirmed the work of previous authors, that the blood cholesterol is raised in hypothyroidism and diminished in hyperthyroidism, failed to find any definite relationship between the blood cholesterol and the basal metabolic rate, although in hypothyroidism there was a rough parallelism between the two. Moreover, they drew attention, with justice, to the fact that much higher figures are found for the blood cholesterol in nephritis than ever occur in hypothyroidism. Whilst,

* Abstract of a paper read before the Liverpool Medical Institution, January 17th, 1929.

therefore, we may agree with Epstein and Lande that chronic parenchymatous nephritis is a metabolic disorder, we cannot take the variations in blood cholesterol as indicating any particular relationship between this condition and hypothyroidism.

The interpretation of the marked increase in blood cholesterol in parenchymatous nephritis is therefore uncertain, but one fact may be mentioned here as offering a possible explanation. Gardner and Gainsborough[8] have shown that the proteins of the blood plasma, especially euglobulin, show a marked affinity for cholesterol, and that removal of the proteins leads to removal of cholesterol with them. In nephritis, particularly the parenchymatous variety, there is a considerable loss of albumin in the urine, which may reasonably be expected to disturb the albumin-globulin ratio of the plasma. This may result in a relative increase of those proteins which show an affinity for cholesterol, and a corresponding increase of cholesterol will appear in the blood. This theory requires investigation.

Cholesterol in Cardio-vascular Disorders.

The majority of workers agree that the blood cholesterol is raised in arterio-sclerosis, and the question arises as to whether the hypercholesterinaemia is related to the arterio-sclerosis as cause or effect. It must be confessed at once that the experimental work on this subject is as yet inconclusive, but several very interesting observations have been recorded, and may with advantage be considered here.

Anitschkow and Chalatov[9] were the first to find that atheroma of the aorta could be produced in rabbits by administration of cholesterol dissolved in sunflower oil. The lesions found by these authors consisted of collections of large mononuclear cells loaded with doubly refracting fat and lying beneath the endothelium. The changes corresponded fairly closely with the earlier stages of human atheroma. Similarly, Scarff[10] fed rabbits on a diet containing cholesterol, and found that if the animals were killed after a few months' feeding of this nature there was extensive atheroma of a type comparable with that occurring in human beings—that is, there were collections of large mononuclear cells loaded with fat beneath the endothelium of the vessels. He observed, further, that if the animals were killed some months after the cholesterol feeding had been discontinued, the lesions resembled very closely the *later* stages of human atheroma, as there was fibrosis of the superficial layers and necrosis of the deeper layers of the vessel wall. Frequently, also, there were crystalline deposits of cholesterol, and splitting of the internal elastic lamella.

Various workers have attempted to reproduce these effects in carnivorous animals, but so far without success. Thus the necessary link between human arterio-sclerosis and that produced experimentally in rabbits is missing. Nevertheless, the association between the two conditions is so striking that the matter must still be left open.

A case reported by Letulle, Labbé, and Heitz[11] illustrates well the clinical association between arterio-sclerosis and hypercholesterinaemia. The arterio-sclerosis was shown to develop in a series of exacerbations, each of which was accompanied by a further rise in blood cholesterol. The exact relationship, however, must still remain *sub judice*.

Under cardio-vascular diseases it must also be mentioned that no rise of blood cholesterol accompanies the oedema of cardiac failure. This is of importance in helping to distinguish, particularly in so-called cardio-renal cases, between oedema of cardiac and that of renal origin, for as it has been seen, oedema due to renal disease is normally accompanied by hypercholesterinaemia.

Cholesterol in Diabetes.

The lipaemia which occurs in severe diabetes is a good indication of the severity of the condition, and as the three principal groups of lipoids—fatty acids, lecithin, and cholesterol—are all increased proportionally, the estimation of one of them will suffice to indicate the degree of lipaemia. Cholesterol is the most stable and easily estimated of the three, and its determination, therefore, affords prognostic guidance of importance.

Treatment of diabetes with insulin diminishes the hypercholesterinaemia, and estimations of cholesterol may be a useful check on the effect of insulin treatment, particularly in cases with marked acidosis. The cause of the hypercholesterinaemia in diabetes is uncertain, but, as I have shown, injections of insulin into the normal rabbit result in a marked decrease in the cholesterol content of the suprarenals.* Thus, if we assume that the suprarenals synthesize cholesterol, its production may be controlled by insulin, and in the absence of an adequate supply of this, such as occurs in diabetes, there will be an uncontrolled production of cholesterol, which will be reflected as an increase in blood cholesterol, whilst the diminution of the hypercholesterinaemia after insulin treatment of diabetes will, on this theory, be due to the inhibited production of cholesterol by the suprarenals.

A practical point arises out of this observation. It has been noted that hypercholesterinaemia may be a factor in producing or aggravating arterio-sclerosis. It is also possible that certain forms of retinitis may be precipitated by its presence. As both of these conditions are common complications of diabetes, it becomes imperative in preventing them to use insulin in such doses that not only the blood sugar, but the blood cholesterol, is kept within normal limits.

Cholesterol in Diseases of the Liver and Bile Passages.

In this group jaundice and gall-stones are the two principal conditions in which variation of cholesterol metabolism is found.

In jaundice due to obstructive lesions there is usually an increase in blood cholesterol roughly proportionate to the intensity of the jaundice, and due, presumably, to the diminished excretion of cholesterol via the bile. This hypercholesterinaemia may serve to distinguish obstructive from haemolytic forms of jaundice, for in the latter there is often a decrease in blood cholesterol. This is seen, for example, in acholuric familial jaundice and in pernicious anaemia, and may be partly accounted for by the concurrent anaemia.

Cholelithiasis early attracted cholesterol workers, because of the almost constant presence of cholesterol in gall-stones, and repeated efforts have been made to show that these stones form as a deposit of cholesterol from blood overcharged with this substance. Thus, Henes[12] and other workers found hypercholesterinaemia in all cases of gall-stones without fever, and assume this to be directly responsible for the deposition of stones. Henes even emphasizes the value of hypercholesterinaemia in distinguishing the dyspepsia of cholecystitis from that of other diseases.

Recent observations by Fowweather and Collinson[13] tend to confirm these findings. They record an increase in the cholesterol concentration of blood and bile in many cases, with an increase of blood calcium in a third of the cases. Usually the cholesterol and calcium were increased in the gall-bladder wall. After cholecystectomy they record a fall in blood cholesterol, where this was previously raised. On these results they postulate "that inflammation of the gall-bladder first leads to obstruction to the outflow of the more or less viscid gall-bladder bile, without any corresponding obstruction to the entry of the thinner bile from the liver. The bile continues to be concentrated in the gall-bladder until it is supersaturated with cholesterol, which it deposits in the form of stones. Further, the concentrated cholesterol solution is partly absorbed through the gall-bladder wall with a resultant hypercholesterinaemia." They also suggest that calcium is deposited in the gall-bladder and forms a nucleus for the stones.

Interesting as these postulates are, the facts on which they are based are not universally agreed. Campbell,[14] for instance, denies that hypercholesterinaemia occurs in gall-stones or cholecystitis unless jaundice be present, and even the figures recorded to show that the cholesterol concentration in the bile in these conditions is greater than normal are of doubtful value, for Fox[15] has shown that the concentration of bile constituents is extremely variable and their estimation difficult. Nevertheless, it is possible, as Blaisdell and Chandler[16] have shown, to produce

* For publication shortly. Work carried out during the tenure of a Beit Memorial Fellowship, and being continued under a grant from the Medical Research Council.

gall-stones experimentally in animals by feeding with cholesterol until a hypercholesterinaemia occurs.

Another factor which appears to be associated with the formation of gall-stones is pregnancy, for gall-stones are undoubtedly common in multiparous women. This factor may act through the disturbance of cholesterol physiology which occurs in pregnancy, since hypercholesterinaemia is often present, and I have recently shown* that in rabbits the cholesterol content of the suprarenals is always greater in does than in bucks, but that during pregnancy the suprarenal cholesterol is depleted.

One other possibility may be considered. If the theory that bile salts are derived from cholesterol should prove correct, any interference with liver function might result in a diminished production of bile salts with a corresponding increase of cholesterol excreted in the bile, and a greater tendency for it to be deposited in the form of stones, either directly from the bile or through the wall of the gall-bladder. This would lay the onus of gall-stone formation on a primary defect in liver function.

To sum up, there seems little doubt from all these facts that the formation of gall-stones is to be attributed to some disturbance in cholesterol metabolism, but the evidence is not sufficient as yet to indicate decisively the nature of this disturbance.

Anaemias.

In pernicious anaemia several authorities have recorded a hypocholesterinaemia, and this is not entirely dependent on the diminished number of red corpuscles—in fact, the blood cholesterol is less in the plasma than in the whole blood.

Pacini[17] considered the low cholesterol values in pernicious anaemia to be a possible cause of the disease, on the ground that haemolysis of the red cells would take place more easily in the absence of the full protective powers of cholesterol. He claimed that inunction with lanoline, which contains a high percentage of cholesterol, was beneficial to the condition. The results, however, were not at all convincing, as the improvement may well have coincided with one of the periods of remission which are common in pernicious anaemia, and, further, the number of cases reported was too small to be of any significance. The majority of workers, however, agree with him in recording low values for the blood cholesterol in this disease. Similarly, in chlorosis and other types of anaemia hypocholesterinaemia is usually found.

In secondary anaemias there is some difference of opinion as to the cholesterol of the blood, some authors recording a hypocholesterinaemia, others no material change. In this connexion it may be noted that extensive haemorrhage, produced experimentally, results in a lipaemia, with its accompanying increase in blood cholesterol, so that it seems probable that the changes in blood cholesterol will vary with the severity of the anaemia and the manner and rapidity of its production. This problem is now being investigated by me. Reference must be made to the interesting work of MacAdam and Shiskin[18] in relation to the anaemias. In addition to their confirmation of the findings of other workers on pernicious anaemia and secondary anaemias, these authors found that in acholuric familial jaundice and splenic anaemia there is a low cholesterol content of the blood, which gradually returns to normal after removal of the spleen. The explanation of this phenomenon is uncertain, but it is interesting to recall the property which the spleen possesses of removing excess of cholesterol from the blood. It is possible that in acholuric jaundice and splenic anaemia the spleen may have this property in an excessive degree, and keep the blood cholesterol at a low level, whilst on removal of the organ a return to normal cholesterol values would be expected.

Another group of cases deserves further investigation—namely, those conditions of splenomegaly which are associated with hypercholesterinaemia, as in the case recorded by Dyke.[19] It is said that Gaucher's disease falls into this class, and various authors have claimed that the histological changes in the spleen characterizing Gaucher's disease can be reproduced by intravenous injections of cholesterol. Others, however, have denied that the histological changes are similar, and further work is required on this problem. I have recently shown[1] that intravenous injections of cholesterol may increase the size of the spleen to twice or three times its normal size. It is thus easy to understand why the spleen becomes enlarged in conditions of hypercholesterinaemia.

The discussion of cholesterol changes in malignant disease, bacterial infections, and formation of lipoid deposits of cholesterol have been omitted from this abstract.

FURTHER OBSERVATIONS ON PNEUMOCOCCAL INFECTIONS.*

BY

C. H. WHITTLE, M.A., M.D.Camb., M.R.C.P.Lond.,

CLINICAL PATHOLOGIST, ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

Primary lobar pneumonia and empyema occurring in previously healthy persons arise from infection with pneumococcal strains of high virulence only. Over 100 strains of pneumococci have now been collected, and the main conclusions reached last year[1 2] have been confirmed.

The Pneumococcal Types in Relation to Disease.†

The distribution of the serological types in relation to the lesion which they caused is given in Table I. Out of a

Table I.—*Showing the Types of Pneumococci Associated with Different Lesions* (Cambridge, 1924-29.)

Lesion.	Type I	Type II.	Type III.	Group IV.	Total No.

total of 47 strains recovered from lobar pneumonia, broncho-pneumonia, and empyema, 33, or 70.5 per cent., belong to Type I; 6 strains, or 12.5 per cent., to Type II; 4, or 8.5 per cent., to Type III; and 8.5 per cent. to Group IV. Such minor lesions as nasal catarrh, conjunctivitis, and

* Summary of an investigation; report to the Science Committee of the British Medical Association, 1929.

† The type agglutinating serums used from 1927 onwards were kindly supplied by the Rockefeller Institute, New York. Previous to this I was using Types I and II serums prepared by Dr. R. R. Armstrong, which were, as I showed from time to time, active agglutinators for the homologous American type cocci at the titres employed in the research.

bronchitis are associated with strains which usually possess a lower order of virulence, and mostly (66 per cent.) belong to Group IV. Type I strains have never been found in this minor kind of lesion. Terminal pneumonia and post-operative pneumonia, arising in persons who are already ill or suffering from shock, are associated with strains which belong only to Type III and Group IV; in 3 out of the 7 cases in Table I they were comparatively avirulent. Type I is therefore the most consistently virulent group, and remains the most important in the production of lobar pneumonia and empyema.

A comparison of the relative virulence of the different types of pneumococci based on the minimal lethal dose for mice is given in Table II. It is again obvious that Type I organisms are consistently of high virulence (the average M.L.D. = 10^{-5} c.cm. of broth culture). Type I is also the numerically predominant group. Type II and Group IV show a relatively low order of virulence, which is in agreement with Gaskell's conclusions.[3]

TABLE II.—*Showing the Virulence and the Relative Predominance of the Different Types of Pneumococci.*

Type.	Proportion of Highly Virulent Strains; M.L.D. = 10^{-5} c.cm. or less.	Proportion of Feebly Virulent Strains; M.L.D. > 10^{-5} c.cm.	Average M.L.D. in c.cm. of Broth Culture.	Total No. of Strains.

Total No. of strains ...	—	—	—	95

During the current year I have been able to obtain 11 strains which appear to belong to Type II. In the first three months of 1929 there occurred in Cambridge a number of cases which were diagnosed as acute bronchitis. The patients, both young and old, presented rather unusual symptoms in that they were often very ill, sometimes for a period of several weeks, although the temperature was never very high. At no time did the physical signs yield evidence of any consolidation of the lung, though broncho-pneumonia was suspected. Nevertheless the prostration, the severity and length of the illness, and the persistent cough with copious sputum suggested some involvement of the alveoli of the lung, and this view was favoured by the fact that one patient contracted an empyema as a complication. It is of particular interest that in the sputa of five of these patients pneumococci were found in great abundance, and that practically pure cultures of pneumococci were obtained which possessed an intermediate grade of virulence. Three of these strains agglutinated with Type II serum and two with Type III serum. I suggest that these strains, which showed a lower order of virulence than the lobar pneumonia strains, were able to set up a particularly toxic form of infection of the bronchioles, which probably extended to patches of lung too small to be differentiated from the rest by percussion and auscultation—a low-grade broncho-pneumonia. The patients all recovered, though slowly. The peculiarly toxic properties of Type II pneumococci have been noted by American workers, and also by Gaskell[3] in his research on experimental pneumonias in rabbits; he found that Type II strains behaved differently from Type I, and that though the amount of lung substance involved in the infection was small the animals were seriously ill for a time and then recovered. These Type II strains were able to set up only minor lesions, yet were highly toxic in their effects. Hence a clear distinction must be drawn between virulence, or the power to grow in the host's tissues, and the power to elaborate toxin.

Such experimental findings indicate a close parallelism between human and experimental infections with Type II pneumococci. The amount of consolidation of the lung in the experimental animals was so trifling as to be unrecognizable by methods of auscultation and percussion.

Conversion of Strains of Low Virulence into Strains of High Virulence.

The question whether strains recovered from such minor infections as nasal catarrh, conjunctivitis, or bronchitis can be converted by laboratory processes into strains of sufficient virulence to produce lobar pneumonia in healthy subjects has been further investigated. A number of strains of this kind have been inoculated into animals by a variety of methods, and with numerous passages, but no appreciable increase of virulence has resulted. The methods used by Griffith[4] for converting his avirulent, "rough" strains back into their virulent, "smooth" phase have been found ineffective. Whereas it is comparatively easy to recover the virulence of strains whose original virulence has been suppressed or temporarily lost, to enhance the virulence of strains which have been from the first of low virulence has so far proved an impossible task.

Pneumococcal Otitis Media Produced Experimentally in Mice.

As noted in my last report,[1] certain feebly virulent strains of pneumococci when inoculated into the peritoneal cavity of mice have occasionally been found to produce a subacute type of infection. This condition has received further study.

Only one mouse out of a dozen inoculated may be affected. The animal usually remains well for as long as a week, but sooner or later it shows signs of inco-ordination pointing to an affection of the semicircular canals. A unilateral effect is produced and the mouse holds its head twisted to one or other side, tends to rotate in the same direction on its long axis when stimulated, and shows a coarse tremor of its head when attempting to move. Occasionally it moves in circles. Usually it dies within seven to twenty-one days after inoculation, and always of pneumococcal septicæmia. Pneumococcal pus is found in one or the other middle and internal ear, sometimes in both, but usually there is more pus on one side than on the other. If the animal is killed before the disease is far advanced one or the other middle ear is found to contain pus which gives pure cultures of pneumococcus and contains no other organism. The heart blood at this stage is usually sterile on culture. The pneumococcus so recovered gives the same serological reactions as the one inoculated into the peritoneum and shows no alteration in virulence.

A similar condition occurring spontaneously in laboratory rats afforded further clues to the anatomical distribution of the lesions in the mice, which was discovered partly by serial sections and partly by cultures and films. In the rats, of which eight have been examined, the symptoms were identical, and pus was found constantly in one or both middle and internal ears. Blood cultures were sterile. In rats the infection appears to run a very chronic course. The organisms obtained from the pus in the ear were not the same in each rat, and they included Gram-negative bacilli, as well as Gram-positive diplococci, which in one case closely resembled pneumococci but were insoluble in bile. A rabbit also showed the same symptoms spontaneously, but unfortunately the animal was thrown away in error before a post-mortem examination could be made.

Laboratory rodents are known to be susceptible to middle-ear infections, but I have been unable to find references to such infections following intraperitoneal injections of pneumococci. It is evident that the middle ear is a site of election for the pneumococcus both in man and in the mouse. I have one case recorded in which otitis media apparently followed a vaginitis in a child of 8. A practically pure culture of pneumococcus was obtained from the vagina and from the ear, and in each instance the strain belonged to Type I and possessed a minimal lethal dose of 10^{-6} c.cm. of broth culture.

The pathology of the mode of infection has yet to be worked out, and I hope to make this research the subject of a separate paper.

Summary.

1. Primary lobar pneumonia and empyema due to pneumococci are invariably caused by strains of high virulence. In the period under examination (1924-1929) 70.5 per cent. belong to Type I.

2. Type II and Type III strains have exhibited relatively great toxicity together with a rather lower order of virulence, particularly noticeable in the first three months of 1929. These organisms may infect a comparatively small amount of lung substance and yet produce a fairly severe and prolonged illness. They therefore differ in their behaviour from the Type I strains.

3. The task of converting strains of low virulence, recovered from cases of nasal catarrh, conjunctivitis, and bronchitis, into those which are sufficiently virulent to set up lobar pneumonia in healthy subjects has again proved impossible by any of the known experimental procedures for raising virulence. No support is therefore given to the theory that these strains of low virulence may become sufficiently pathogenic to produce pulmonary lesions, though such a possibility cannot be finally excluded.

4. A condition of subacute otitis media with involvement of the semicircular canals has been set up in mice by the introduction of pneumococci of moderate or feeble virulence into the peritoneal cavity. The condition bears the closest resemblance to the spontaneous otitis media occurring in laboratory rodents. Though the pathology of the infection has not been worked out in detail, it is clear that the pneumococcus has a special predilection for the middle ear both in man and mouse.

I wish to thank Dr. J. F. Gaskell for his frequent advice, and Professor W. E. Dixon both for the hospitality of his laboratory and for help in drawing up this report. I wish also to record my gratitude to the British Medical Association for the generous assistance afforded me by a grant for the research.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

CONTINUOUS DRAINAGE OF A HYDRONEPHROTIC ONLY KIDNEY.

THE following case of a patient who for seven years has passed urine through a catheter introduced into the renal pelvis by way of a lumbar incision is, I think, instructive enough to deserve recording.

On August 12th, 1922, I was called to see a married woman, aged 45, who gave a history of complete anuria for two days. She had had no pain or vomiting, and was not feeling ill; her temperature and pulse were normal. Examination revealed no distension of the bladder, but there was a large, tender, tense swelling in the left lumbar region. In the right loin there was an old scar, and the right kidney could not be felt; I was informed that the kidney had been removed at the Westminster Hospital ten years previously for tuberculous disease. The patient stated that during the whole of the intervening period she had been free from urinary symptoms. No evidence of tuberculous disease was found elsewhere.

The patient was admitted to the Hornsey Central Hospital, where catheterization proved that the bladder was empty, and the diagnosis of hydronephrosis of a single kidney was made.

I operated as soon as possible, exposing the left kidney through a lumbar incision, and found the pelvis distended with nearly a pint of clear urine, which I drained by a tube passed through the cortex. The renal tissue appeared normal, and there was no evidence of stone or tuberculous infection. The patient made a good recovery.

During the three days following the operation urine drained freely through the tube, and a small quantity passed naturally. On the fourth day the tube became dislodged and could be replaced only with great difficulty. As the patient remained free from pain and passed normal quantities of urine through the bladder, the wound was allowed to heal. A radiogram revealed no stone or other abnormality, and the patient returned home apparently well after three weeks.

All went well until the end of the following September, when the condition returned, though the swelling was much smaller than on the previous occasion. I operated again within twenty-four hours, and once more the patient made a good recovery. This time, however, fearing a further return of the obstruction, I decided to attempt prolonged or permanent drainage, and at the end of a fortnight, when the wound had nearly healed, I replaced the tube by a No. 12 rubber catheter. Later Messrs. Bailey and Son fitted a rubber belt and urinal into which the catheter drained.

The patient has now worn this apparatus for seven years. She is able to remove and cleanse it unaided, and suffers no inconvenience from leakage. Only occasionally an ounce or two urine is passed naturally. The urine is usually alkaline, sometimes contains a considerable deposit of pus, but it quickly improves with the use of acid sodium phosphate. During the whole of this period the patient has led an active life, doing her own housework. Her condition compares very favourably with the best I have ever seen after suprapubic drainage of the bladder.

The case presents the following interesting features: the excellent results of the nephrectomy for unilateral tuberculosis seventeen years ago; the coincidence of hydronephrosis from unknown but probably congenital causes in a solitary kidney; the continued functioning of the kidney after pressure and repeated injury; and the comfort of the patient under these conditions.

London, N. FRANK MANNINGTON, F.R.C.S.Eng.

FOREIGN BODIES SWALLOWED INTENTIONALLY.

THE following case is unusual and seems worthy of placing on record.

The patient, a man aged 27, was admitted to this hospital on April 2nd, 1929, with the history that while in prison in September, 1928, he swallowed a piece of copper wire about 4 inches long,

Skiagram taken on April 3rd (reversed in reproduction).

large needle about the same length, and a dinner fork. He was operated upon and the fork was removed during September, 1928. While still in prison, on March 5th, 1929, he swallowed another fork, which had not been removed.

On examination directly after admission the patient appeared to be well developed and nourished. An upper abdominal mid-line scar from the previous laparotomy was seen. Nothing abnormal was discovered on abdominal palpation except some general thickening in the epigastric region. Under *x*-ray examination the fork was shown apparently in the stomach. An article like a needle was seen in the upper right quadrant of the abdomen. The piece of copper wire was seen in the region of the descending colon.

On April 7th the abdomen was opened, the old scar being excised. A general examination of the stomach and the abdominal cavity was then made. An adhesion was found running from stomach to liver; when this was divided it was found to have a piece of metal in its midst. This, on close examination, proved to be the remainder of the needle swallowed in September, 1928. The fork, a large dinner one, 7½ inches long, was found to be lying with the handle at the pyloric end of the stomach. A small incision was made in the stomach over the handle and the fork extracted. The opening in the stomach was then closed. Next, a search was made for the third foreign body seen in the radiogram. The colon was especially subjected to close examination, but no trace of this foreign body could be found. The abdomen was then closed.

The patient made a satisfactory recovery and was discharged from hospital on May 1st.

On examining the fork after the operation, the handle half was seen to be unaffected by its long stay in the stomach, but the other half, which had been pointing towards the cardiac end, was corroded and black in colour.

I am indebted to Mr. H. Morton Anderson and Dr. William Graham for permission to publish this case.

DONALD A. P. MACALISTER, M.B., F.R.C.S.Ed.,
Assistant Medical Officer, Gulson Road Hospital, Coventry.

ACUTE JEJUNAL PERFORATION ASSOCIATED WITH CARCINOMA OF THE STOMACH.

THE following case presents an unusual combination of conditions, and seems worthy of record.

The patient, a man aged 56, was admitted to St. Mary's Hospital on July 8th, 1929, with symptoms, dating from September, 1928, of loss of weight, indigestion with increasing frequency of vomiting, and marked pallor. There was some epigastric tenderness, but no palpable tumour, on examination. The radiological report showed that there was great delay in the emptying time of the stomach, owing to organic obstruction.

On July 15th the patient was operated upon by Professor C. A. Pannett, and a pyloric carcinoma was found with many adhesions to surrounding structures, rendering excision impracticable. A palliative anterior gastro-jejunostomy was performed. The patient was then comfortable for three days, when vomiting started. This was unrelieved by repeated gastric lavages, and at noon on July 23rd Professor Pannett performed a lateral anastomosis (jejuno-jejunostomy) between the limbs of the loop taken for the previous anastomosis. There was no distension of the afferent limb, and the cause of the vomiting was not clear. The patient was comfortable throughout the afternoon and evening, and slept well. At 7 a.m. on July 24th there was a sudden collapse, the pulse rate rising rapidly and the pallor increasing. The condition became worse, and the patient died twenty-four hours after the second operation.

At the necropsy the findings were as follows: (*a*) Stomach wall dilated and pale. (*b*) Pale annular growth stopping short at the pylorus spreading 5.5 cm. in the stomach wall from the pyloric ring. Centrally in the mass was an ulcer measuring 3.5 by 2 cm. (*c*) Opposite the second anastomosis performed twenty-four hours before death, and at a distance of 1.5 cm. from it, there was a clean-cut perforation, the size of a little fingernail, in the distal limb of the jejunal loop. (*d*) On section the tumour was found to be a tubular columnar-celled carcinoma.

In view of the short history, it would seem that the carcinoma did not arise from a previous gastric ulcer. The cause of death must certainly have been due to this jejunal perforation, which was so acute as to have become complete within twenty-four hours.

E. ROHAN WILLIAMS, M.R.C.S., L.R.C.P.,
House-Surgeon to Surgical Unit, St. Mary's Hospital, London.

CASE OF SUSPECTED RAT-BITE FEVER.

THE following are some notes of a rather unusual type of infectious disease recently treated at Lochmaben Combination Hospital.

The patient, who was 23 years of age, was a nurse in a private institution. The history was that on the night of June 7th she awoke suddenly and found blood running down her neck from a wound in the lobe of her right ear. She felt no pain, saw no animal or insect of any kind, and did not know what had awakened her. Three days later her ear began to swell, and became very painful. The swelling spread to the cheek, and the lobe of the ear became inflamed, the severe pain persisting. She felt very ill and extremely weak, and apparently had a high temperature. Seven days after the first symptoms appeared, a smear from the ulcerated area was sent to a laboratory, and the verdict was stated to have been returned as "erysipelas." Consequently the patient was admitted to Lochmaben Combination Hospital on June 21st, labelled "erysipelas." The condition then present was that of severe ulceration of the right ear and a large tense swelling in the region of the right parotid. Neither then nor at any other time during the illness was there any enlargement of the lymphatic glands.

On admission the patient did not look very ill, her temperature was normal, and she did not complain of much pain. She was put on the usual erysipelas treatment without benefit. Five days after admission, on June 25th, the temperature rose to 101° F., and the next day to 103° F. The ulcerated area became angrier in appearance and very painful, and several large indurated bluish-red papules, not unlike those seen in erythema induratum, appeared on the trunk and limbs. The patient now felt very weak and looked very ill. An interesting feature was that from time to time she complained of pains in the calves, these being the only muscular or joint pains reported. The next day the temperature fell sharply to normal, the patient felt much better, and the papules had faded very considerably. Within a few more days the papules had almost entirely disappeared, the only traces left being livid patches of skin with a certain amount of coarse desquamation. Exactly one week later the same series of phenomena reappeared and were again repeated at two further intervals of eight and six days. By this time (July 17th) the parotid swelling had practically disappeared, and the ear was almost entirely healed. Blood film examination showed no abnormality. The febrile attacks, however, were obviously becoming more severe, and in consultation with Dr. Ritchie, county medical officer of health, it was decided that the infection must be protozoal in origin. It was therefore decided that blood should be withdrawn for cultural and microscopic examination, and for guinea-pig inoculation, at the time of the next periodic rise of temperature. Consequently this was done by Dr. Armstrong, county bacteriologist, on July 25th. This part of the investigation, however, proved unsuccessful, all the tests being uniformly negative. Unfortunately there were no white mice or rats available for inoculation.

It was now decided to give one or more intravenous injections of neokharsivan two days before the next expected rise of temperature, but a most curious condition prevented this. After the withdrawal of blood from the veins of both arms for investigation, a hard, scaly dermatitis developed over the skin where the venipuncture had been made, completely preventing the location of a vein for the proposed injection. Consequently the patient had a rise of temperature at the expected time, and the intramuscular route was had recourse to for the arsenical medication. Sulpharsenobenzol in an initial dose of 0.3 gram was injected into the thigh on August 7th, two days before the next expected febrile attack. Two days later the patient's temperature rose to 99° F., and fell to normal next day. One week later another 0.3 gram of sulpharsenobenzol was injected intramuscularly, and from thence onward the patient remained completely afebrile. A final dose of 0.45 gram was given the following week. The patient kept perfectly well throughout the course of treatment, and felt no bad effects after the injections. She was discharged on August 30th, apparently in a perfectly fit condition and with no sign of the original ulceration left.

It is unfortunate that the blood investigation failed to yield the necessary proof of the condition, but there appears to be little doubt that this was a sporadic case of rat-bite fever. A point of some interest is that Dr. Ritchie saw a very similar case in a child in Dumfriesshire, where the symptoms were more severe and included cervical adenitis as a prominent feature during the periodic febrile attacks. This case was reported jointly with Dr. T. Reid by Dr. Ritchie in the *Edinburgh Medical Journal* in 1915.

WILLIAM CLUNIE HARVEY, M.D., D.P.H.,
Resident Medical Superintendent.

Reports of Societies.

METHODS OF DIAGNOSIS IN GASTRIC DISEASE.

AT the meeting of the Medical Society of London, on November 11th, with the president, Mr. DONALD ARMOUR, in the chair, a discussion was held on "The relative value of the different methods of diagnosis in gastric disease."

Clinical Examination.

Dr. J. A. RYLE said that the merits of the several diagnostic methods must vary with the disease, the stage of the disease, the case, and not a little with the outlook and experience of the physician or surgeon in charge. At present there was uncertainty in the minds of the profession as to the types of cases which were suitable for, and were benefited by, an investigation by modern methods. It constantly fell to his lot to see cases which had been investigated radiologically, but in which this investigation should have taken place much earlier, or had been inadequate, or the findings wrongly interpreted. He also saw cases which had been quite unnecessarily x-rayed. The shortcomings lay sometimes with the clinician, sometimes with the radiologist, but often the collaboration between the two was less close than it should have been. Again, in suspected organic disease of the stomach too little use was being made of chemical investigation, though misinterpretation of the findings was relatively rare. The clinical method was in every case, and without exception, the most important. The introduction of accessory methods had at first led to a certain neglect of the older clinical procedure. The availability of radiology and chemistry had been a handicap as well as a boon to clinical medicine; judgements had been warped, and wrong conceptions had arisen. Moreover, an impatient and uninstructed public was now beginning to demand these accessory investigations, often with inadequate reason. If the profession bowed to such dictation at the expense of clinical medicine it would be guilty of a disservice. The clinical study of the dyspeptic should include, first, an inquiry into personal and family history, a very careful inquiry into subjective symptoms, observations on physical and psychological type, a general overhaul of the systems, and a special examination directed towards the abdomen and digestive apparatus. The collection and analysis of symptoms was, as a rule, the most important of the lines of inquiry. Flatulence,

heartburn, nausea, acid eructations, and vomiting all called for appraisement. Family history was of real diagnostic value in duodenal ulcer and gall-stones. Personal history in so far as it related to age, sex, occupation, habits, seasonal fluctuations of the dyspepsia, and food or drink idiosyncrasies was clearly of outstanding importance. Worry, fatigue, and sedentary work were potent agents in gastric disturbance. Nervous and anxious or phlegmatic temperaments were associated with special types of gastric reaction. The general overhaul might reveal much. The skin and musculature of the abdomen, its conformation and contours, as well as any tender points, should be noted as items in a routine survey. Teeth, tongue, and fauces should be carefully inspected. Such a survey should suffice to place the case in one of the following groups, the classification of which was based on causation rather than on symptomatology.

1. Habit dyspepsias: examples, over-eating, under-eating.
2. Nervous or psychological dyspepsias, due to faulty mental or nervous adjustment.
